This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

COMPOSITION AND ELECTROTYPING BY THE
STANHOPE PRESS, BOSTON, MASS.

PRINTING AND BINDING BY
BRAUNWORTH & CO., BROOKLYN, N. Y.

PREFACE

There is a considerable literature of mining, comprising
graphs, papers published in the transactions of engi
tments of the mining periodicals. The treatises and
ive, and are intended chiefly for students. Among
of Foster, Hughes, Haton de la Goupillière, Köhler, C
son, Bulman and Redmayne, Bailes, Boulton, and Pam
books are antiquated in their engineering features, s
those of Callon and Haton) contain much that is still
neers would do well to have acquaintance with them.
Also there are the more recent monographs of Truscott,
Denny, on the Witwatersrand goldfields, Charleton's
ed." Hoover's "Principles of Mining," Finlay's "Cost
ber of useful books on specific subjects relating to mi
nical engineering of mines.

A valid reason for bringing out a new Mining Engineer's
ed in the fact that the two already in existence either
ver, many subjects which constitute important parts
ipment of the present day mining engineer. It will be
ry examination of the following pages, that a handbo
s a greater variety of subject matter than books o
neering, and that the field to be covered is too wide to
fully by a single writer within any reasonable period of
In February and March, 1913, the Editor of this book c
ents, and invited a number of Associate Editors to co
r respective specialties. Besides those sections dealin
deposits, methods of prospecting, exploration and minin
minerals, there are others on certain branches of civil, electr
neering. It may be thought by some that this collater
much space in a book on mining. But, in view of the im
the allied branches of engineering in equipping and opera
Editor believes the allotment of space is reasonable. H
et the demands not only of engineers concerned with th
agement of mines, but also of the large number of thos
with, and greater interest in, the construction details invo
of plant. Therefore, the aim has been to supply such
wer plant, electric transmission and structural design, as
and when in the field and out of reach of his personal
ary. For office use, there is at the end of each section a
these important books and papers on the subjects dealt with
practice, no well-defined boundary exists between the f
ning engineer and the metallurgist. While, under some
ver regions, the mining engineer's functions end with the
ct to delivery to a custom reduction works (mill or smelter
ucing company's plant includes a concentrating mill, amalg
ng works (as at many gold and silver mines), or even a smel
to planning the book, the question arose as to how much sp
e given to the processes of ore treatment. To cover any
e great field of modern metallurgy would be impracticable

the work far beyond the limits of a single volume. Realizing that the urgent need of a companion Handbook of Metallurgy must soon be supplied, it was decided, as a compromise, to furnish condensed summaries of those processes of treatment which are frequently carried on by mining companies themselves. The book, therefore, contains sections on ore-dressing, ore-testing, gold amalgamation, an outline of the cyanide process, the preparation of anthracite, bituminous coal and coke, and a brief résumé of certain facts respecting the selling, purchasing, and metallurgical treatment of ores, that are of immediate interest to the engineer in control of mining operations.

The relatively small space allotted to coal mining is due chiefly to three considerations: first, a Coal-mining Pocketbook is already in existence; second, metal-mining methods are more varied than those for coal, due to the greater diversity in form and occurrence of metalliferous deposits; third, having discussed in Section 10, under Metal-mining Methods, the operations common to nearly all mining, the articles on coal mining are properly confined to the methods and data peculiar to that branch of the industry.

The question of supplying cost data is difficult. A large number of itemized tables are included in the sections on Cost of Mining, Exploitation of Mineral Deposits, Boring, and other subjects, but costs of machines and apparatus are given sparingly throughout the book. This has been judged best, because of frequent price changes, and the great diversity of types of mechanical plant. In any case, to make close estimates, the engineer must apply to the makers for current prices. In some parts of the book, the names of machinery builders have been used freely, but without intention to indicate a preference for the product of any particular maker.

While the Editor has aimed to make the style and arrangement uniform, he has had good reason to realize the difficulty of securing consistency in these matters, considering the heterogeneous nature of the subject matter, and the fact that it has been written or compiled by so large a corps of Associate Editors. In these circumstances, unity and evenness of treatment can hardly be expected, but an endeavor has been made to observe a reasonable proportion between the length of each section and its relative importance. To save space, abbreviations are employed for a few words in common use by engineers, and chemical elements and compounds are generally represented by their symbols.

The thanks of the Editor are due to members of the staff for their painstaking work, in many cases carried on in the intervals between pressing professional engagements in the field, and to the Publishers for their liberal spirit of coöperation in facilitating the preparation of the book. The Editor desires to express his especial appreciation of the valuable suggestions and assistance in revising manuscript and correcting proof, of Professor Edward K. Judd, of the Columbia School of Mines. It was planned to publish this book in 1916. The breaking out of the Great War, about one year after the work was begun, is responsible in large measure for the delay.

ROBERT PEELE

SCHOOL OF MINES,
1917

CONTENTS

1. Mineralogy. By Alfred J. Moses, Professor of Mineralogy, Columbia University

1–4.	Identification of Minerals	Pages 2–11
5–8.	Occurrence and Associations of Minerals	11–13
9–12.	Uses of Minerals	13–15
	Descriptive and Determinative Tables	16–71

2. Geology and Mineral Deposits. By James Furman Kemp, Professor of Geology, Columbia University

1–12.	Geology	Pages 74–93
1–12.	Mineral Deposits: Ores	94–106
13–26.	Mineral Deposits: Non-metallic Minerals	107–114

3. Earth Excavation. By Halbert P. Gillette, Consulting Civil Engineer

1–13.	Excavation by Manual Labor and by Machinery	Pages 117–142

4. Explosives. By H. G. Haskell, Fletcher B. Holmes, Arthur La Rue and F. J. LeMaistre.

1–5.	Chemistry and Composition	Pages 143–151
6–8.	Transportation and Storage	151–160
9–12.	Handling, Charging, Firing, etc	160–177

5. Rock Excavation. By Halbert P. Gillette, Consulting Civil Engineer

1–6.	Hand and Machine Drilling	Pages 179–191
7.	Charging and Firing	192–195
8–12.	Hauling, Quarrying, Trenching, etc	196–205

6. Tunneling. By David W. Brunton and John A. Davis, Consulting Mining Engineers

1.	Data on Representative Tunnels	Pages 207–211
2–12.	Drilling and Blasting	212–228
13–15.	Mucking, Timbering, and Costs	229–246

7. Shaft-sinking in Rock. By Homer L. Carr, Mining Engineer

1–3.	Cross-section and Size of Shafts	Pages 249–250
4–12.	Sinking Plant. Organization. Drilling and Blasting	251–261
13–17.	Sinking in a Working Shaft. Shaft "Raising"	261–262
18.	Timbering and Lining	262–272
19.	Kind-Chaudron Process	273–275
20–23.	Speed and Cost Data	275–281

8. Shaft-sinking in Soft, Water-bearing Soils. By Francis Donaldson, Mechanical Engineer

1–2.	Timbering and Spiling Methods	Pages 283–288
3–5.	Open and Pneumatic Caissons	288–301
6–11.	Freezing and Grouting Processes	301–306

9. Boring. By Arthur F. Taggart, Assistant Professor of Mining, Sheffield Scientific School, Yale University

1–4.	Boring by Hand	Pages 307–314
5–15.	Churn Drilling	314–338
16–18.	Rotary Drilling (Diamond and Shot-boring)	338–368
19–19.	Survey of Boreholes, etc	369–376

Sec 10. Prospecting, Development and Exploitation of Miner posits. By James F. McClelland, Professor of Mining, Sheffield tific School, Yale University

Art 1–14.	Prospecting and Exploration	Pages
15–23.	Development	
24–28.	Classification. Breaking Ground	
29–44.	Open Stopes	
45–58.	Timbered Stopes	
59–67.	Filled Stopes	
68–70.	Shrinkage Stopes	
71–75.	Top-slicing	
76–79.	Sub-level Caving	
80–83.	Block-caving	
84–89.	Combined Methods	
90–94.	Miscellany, Underground Mining	
95–101.	Open-cut Mining	
102–111.	Coal Mining Methods	
112–115.	Subsidence	
116–127.	Placer and Hydraulic Mining, Gold Dredging, Drift Mining	

Sec 11. Underground Transport. By Edwin C. Holden, Minin gineer

Art 1–2.	General Considerations and Primitive Methods	Pages 8
3–8.	Mine Cars and Track	8
9–10.	Hand Tramming and Animal Haulage	8
11–16.	Locomotive Haulage	8
17–20.	Rope Haulage. Miscellaneous. Costs	8

Sec 12. Hoisting Plant, Shaft Pockets and Ore Bins. By Willia Weigel, Associate Professor of Mining, Pennsylvania State College

Art 1–2.	Windlass and Whim	Pages 8
3–12.	Hoisting Engines	8
13–15.	Hoisting Ropes and Sheaves	9
16–18.	Headframes	9
19–20.	Guides, Signals, etc	9
21–27.	Buckets, Cages, and Skips	9
28–30.	Shaft Pockets and Surface Ore Bins	9

Sec 13. Drainage of Mines. By Robert Van Arsdale Norris, Cons Mining Engineer

Art 1–5.	Sources and Control of Mine Water	Pages 993
6–17.	Pumping and Hoisting Water	1001

Sec 14. Mine Ventilation. By F. Ernest Brackett, Mining Engineer

Art 1–3.	Mine Atmosphere and Its Impurities	Pages 1019
4–9.	Distribution and Control of Ventilating Currents	1024
10–11.	Natural and Furnace Ventilation	1038
12–18.	Mechanical Ventilators	1044

Sec 15. Compressed-air Plant. By Richard T. Dana, Consulting Engi

Art 1–9.	Compressors and Their Operation	Pages 1061
10–15.	Valves, Governors, Cooling Devices, etc	1079
16–20.	Transmission, Measurement and Reheating of Compressed Air	1084
21–23.	Compressed-air Hoists and Pumps	1092
24–29.	Machine Drills, Coal Cutters and Compressed-air Locomotives	1099

11. Electric Power for Mine Service. By George R. Wood, Electrical Engineer, Berwind-White Coal Mining Co

1–5. Purchased Power. Choice of Current and Voltage..... Pages 1124–1126
6–8. Buildings and Plant..... 1126–1132
9–11. Surface and Underground Transmission Lines..... 1132–1137
12–15. Hoisting, Haulage and Pumping..... 1137–1149
16–17. Miscellaneous Applications..... 1149–1159

12. Surveying. By Charles B. Breed, Professor of Railroad Engineering, Massachusetts Institute of Technology

1–5. Surveying and Drafting Instruments..... Pages 1161–1180
6–17. Land Surveying..... 1180–1202
18–21. Leveling and Contours..... 1202–1209
22–30. Topographic and Railroad Surveying..... 1210–1223

13. Underground Surveying. By Edward K. Judd, Assistant Professor of Mining, Columbia School of Mines

1–2. Stations, Illumination, Transit Mountings..... Pages 1224–1229
3–7. Horizontal and Vertical Angles. Traversing and Leveling..... 1229–1243
8. Shaft Plumbing..... 1243–1249
9–12. Notes, Computations and Maps..... 1249–1253

14. Mine Geologic Maps and Models. By Reno H. Sales, Geologist, Calumet Copper Mining Co

1–12. Maps and Models..... Pages 1254–1267

15. Mine Organization and Accounts. By J. R. Finlay, Consulting Mining Engineer

1–2. Organization..... Pages 1268–1273
3–6. Mine Records and Accounts..... 1273–1281

16. Cost of Mining. By J. R. Finlay, Consulting Mining Engineer

27 Examples, Comprising 118 Tables of Costs..... Pages 1283–1354

17. Wages and Welfare. By Edward K. Judd, Assistant Professor of Mining, Columbia School of Mines

1–7. Day's Pay, Contract Work, Leasing, etc..... Pages 1356–1362
8–11. Accident Compensation. Arbitration..... 1362–1369
12–13. Change Houses and Miners' Dwellings..... 1369–1373
14–16. Domestic Water Supply. Sanitation. Miners' Diseases.. 1373–1381

18. Mine Air, Hygiene, Explosions, and Accidents. By George S. Rice, Chief Mining Engineer, U S Bureau of Mines

1–4. Mine Air..... Pages 1383–1397
5–8. Mine Hygiene..... 1397–1407
9–11. Lamps and Apparatus for Determining Impurities in Mine Air..... 1407–1420
12–16. Accidents and Their Prevention..... 1420–1447
17–20. Rescue and Recovery Work..... 1447–1460
21–26. Mine Safety Organization and Regulations..... 1461–1465

19. Mining Laws. By Horace V. Winchell, Mining Geologist

1–2. Introduction and Theories..... Pages 1468–1469
3–13. United States Mining Laws..... 1469–1485
14–27. State Laws..... 1485–1498
28–38. Summary of United States Laws..... 1498–1514

Sec 25. Mine Examinations, Valuations and Reports. By Young Westervelt, Consulting Mining Engineer

Art 1–3. General Considerations, Geology, Maps, Titles..... Pages 1
4–10. Theory and Methods of Sampling..... 1
11–12. Determination of Quantity and Value of Ore..... 1
13–15. Market Prices of Minerals, Profits, Capital, etc..... 1
16–17. Conduct of Examinations and Writing of Reports..... 1
18. Estimating Standing Timber..... 1

IDENTIFICATION OF MINERALS

1. Definitions

On the basis of several thousand analyses the crust of the earth for a of about ten miles is estimated by Clarke, "*Data of Geochemistry*," p. 3 composed almost entirely of compounds of fourteen elements:

	Per cent		Per cent		
Oxygen	49.78	Sodium	2.33	Chlorine	
Silicon	26.00	Potassium	2.28	Carbon	
Aluminium	7.51	Magnesium	2.24	Phosphorus	
Iron	4.21	Hydrogen	0.95	Sulphur	
Calcium	3.39	Titanium	0.37	Total	

These great elements, and the sixty or so others which form the ren fraction of one per cent, occur in approximately one thousand different cal combinations, known as minerals; that is, as *homogeneous substa definite chemical composition, found ready-made in nature, and not dir product of the life or decay of an organism.*

The two conditions in which minerals may occur. A miner other chemical substances, will usually occur either in crystals of charac shapes or in masses made up of many crystals so crowded together tl shapes are not evident, although in each grain of the aggregation the cry structure will be shown by the constancy of the properties in parallel dir and their variation in directions not parallel.

Any mineral may in solidifying fail to assume a crystalline structure, b of too great viscosity, or too rapid cooling, or other cause. If this cond invariable, the mineral is said to be *amorphous*. Opal is the best ex Amorphous minerals are few in number.

2. Identification by Aid of Crystals

The crystalline structure is much used in the identification of minerals, by a consideration of the symmetry and angles and habit of the external or by the study of properties dependent on the structure, particularly cle and the so-called optical characters and etch figures.

Symmetry. In every complete crystal there is some repetition of and similarly grouped faces. By considering this so-called "symmetry" tals may be grouped in divisions, and as all crystals of any one mineral the same grade of "symmetry," they belong to the same symmetry divis

In identifying an axis of symmetry imagine or actually cause the crys revolve about some prominent line through its centre. Note the groupi faces at the initial position. Note whether at any stage of the revoluti crystal faces appear to be all coincident (rarely), or all parallel to the positions of other faces. Or, in other words, note whether groups of fac replaced during the revolution by other groups containing just as many at exactly the angles of the first set. If so, a probable axis of symmetr been determined. If by measurement the angles of one set correspond in and order with those of the other sets, then the existence of the symmetry is confirmed. According to the number of times corresponding groups or recur during a complete revolution about a symmetry axis the axis is kno two-fold, three-fold, four-fold, or six-fold. No other varieties exist.

If a plane so divides the crystal that on each side of that plane ther

...ed the same number of faces at the same angles to it and to each other, ...ane is called a Plane of Symmetry.

...visions or "systems" based on symmetry. The following seven ...es result readily from this partial determination of symmetry, the state- ...s not implying the absence of other symmetry elements:

1.	Isometric.....	More than one axis of three-fold symmetry. (Often also more than one of four-fold.)
2.	Tetragonal.....	One axis of four-fold symmetry and one only.
3.	Hexagonal.....	Rhombohedral division — one axis of three-fold symmetry and one only.
4.	Hexagonal.....	Hexagonal division—one axis of six-fold symmetry.
5.	Orthorhombic.....	Three axes of two-fold symmetry, but nothing higher than two-fold; or one axis of two-fold symmetry at the intersection of two planes of symmetry.
6.	Monoclinic.....	One axis of two-fold symmetry and one only, or one plane of symmetry, or both.
7.	Triclinic.....	Without axes or planes of symmetry.

...tinguishing species by angles. Although different crystals of the ... substance may differ in shape, angles, and number of faces, the angles be- ...*corresponding* faces are constant and characteristic.

...responding faces on the same crystal, or on different crystals of the same substance, ...corresponding or analogous positions with reference to the symmetry axes and usu- ...correspond in lustre and markings. They frequently do not correspond in shape.

...e measuring of a few selected angles will, therefore, usually serve to differ- ...ate the crystal from others in the same symmetry division.

...les may be determined within one or two degrees by a very simple apparatus, ...as the Penfield No. 2 goniometer, consisting of a cardboard on which is printed a ...ded semicircle, with an arm of celluloid swiveled by an eyelet in the centre of the ...ircle, or better a similar apparatus of metal with removable and adjustable arms. ...the crystal is placed so that the card edge and the swinging arm, or the two ...arms, are each in contact with a face and perpendicular to the edge of intersection ...two faces, and the mean of at least three readings is used.

...e "cleavage" directions, obtained as described later, are of great service in orien- ...ing the crystal. These and the angles between them are used in the lists which follow ...them.

...nes are composed of faces all parallel to the same line. Their intersections are ...e parallel to this line and to each other.

...sometric crystals. If a crystal shows more than one axis of three-fold ...metry it is an isometric crystal, and not otherwise. There will always be ...also, axes of two-fold or four-fold symmetry. The faces are often ...s and equilateral triangles, or these modified by cutting off corners. The ...ns are usually approximately equal in several directions, the forms ...ing sometimes to the sphere. Repetitions in any crystal of equal angles ..."corresponding" faces are more frequent than in other crystal systems.

...gles. These are of the same series whatever the species. The important species ...ed by their "habit"; that is, the dominant forms of the crystals, as follows:

...tahedral. (Tetrahedron angles, 70° 31′) boracite, sphalerite, tetrahedrite.

...: *With easy cubic cleavage:* cobaltite, galenite, halite; *with octahedral cleavage:* flu- ...rite; *without marked cleavage:* argentite, boracite, cerargyrite, cuprite, pyrite.

...tahedral. (Octahedron angles, 109° 29′) chromite, cobaltite, cuprite, fluorite, ...galenite, gold, linnæite, magnetite, pyrite, spinel. Cleavages: galenite, ...rite, octahedral. Partings: franklinite and magnetite, octahedral.

Dodecahedral. (Dodecahedron angles, 120°) boracite, cuprite, garnet, m sphalerite.

Trapezohedral. (24-faced trapezohedra, approximating spheres; common 131° 19′, 146° 27′) analcite, garnet, leucite.

Pyritohedral. (12-faced pyritohedra; most common angles, 126° 53′ and cobaltite, pyrite, smaltite.

Tetragonal crystals. If the crystal shows one axis of four-fold sym and only one, it is a tetragonal crystal, and not otherwise. A section t right angles to the four-fold axis is usually square or octagonal, or more the angles are again truncated. The dimension in direction of the fo axis is usually notably greater or less than in directions at right angles t

Angles. In the zone of faces parallel to the four-fold axis there are no varia angle dependent on the species. Between prominent *corresponding* faces the an almost always 90°, and between prominent *adjacent* faces either 90° or 135°. T acterizing angles lie in other zones.

The principal tetragonal minerals may be classified by angles and cleavage as Angles between corresponding faces *oblique to the four-fold axis:* chalcopyrite, wulfenite, 99° 38′; scheelite, 100° 5′; apophyllite, 105°; braunite, 109° 53′; cas 121° 41′; rutile, 123° 8′; zircon, 123° 19′; vesuvianite, 129° 21′; wernerite, 136° Braunite, scheelite, and wulfenite cleave at the angles mentioned. Werneri rutile cleave parallel to the four-fold axis, giving angles of 90° and 135°. Apo cleaves at right angles to the four-fold axis.

Hexagonal crystals. If the crystal shows one and only one axis of fold symmetry it is a hexagonal crystal, rhombohedral division. crystal shows one and only one axis of six-fold symmetry it is a hex crystal, hexagonal division. A section taken at right angles to the three-fold or six-fold symmetry is usually a hexagon, or its most pro edges form an equiangular triangle or a hexagon. Not infrequently each is replaced by one or two smaller edges. The dimension parallel to this usually notably greater or less than the dimensions at right angles thereto.

Angles. In the zone of faces parallel to the three-fold (or six-fold) axis there variations in angle dependent on the species. The angles between prominent sponding faces are chiefly 120° or 60°. Other angles in this zone are usually large an occurrence leads to an apparently rounded, often nearly circular, cross-section. characterizing angles lie in other zones.

The crystals of important hexagonal minerals may be classified by angles betwe responding faces and by cleavage as follows:

I. With evident axis of three-fold symmetry and usually rhombohedral h

Angles which are both interfacial and between cleavage directions. Soda 73° 30′; chabazite, 85° 14′; hematite, 86°; calcite, 105° 5′; dolomite, 106° 15′; chrosite, 107°; siderite, 107°; magnesite, 107° 24′; smithsonite, 107° 40′; proustite, 10

Angles which are interfacial only. Ilmenite, 85° 31′; alunite, 90° 50′; cin 92° 37′; willemite, 115° 30′; phenacite, 116° 36′; tourmaline, 133° 8′ or 103°.

II. With real or apparent axis of six-fold symmetry, and usually prismatic

Prisms capped by faces oblique to axis and at angles, for example, corun 86° 4′ or 128° 2′; quartz, 94° 14′ or 133° 44′; apatite, 142° 15′.

Prisms usually capped by single face at right angles to axis. Beryl, iod mimetite, nephelite, pyrargyrite, pyromorphite, vanadinite.

Tabular. Graphite, molybdenite, iridosmine.

Orthorhombic crystals. If a crystal shows either three axes of two symmetry or one axis with two planes of symmetry, and nothing of hi symmetry, it belongs to the orthorhombic system. Cross-sections take right angles to the axes of symmetry are unlike in angles, and tend to angles and rhombs or to these combined.

Angles. There is no zone of faces which has a constant series of angles for all species. The interfacial angles in the zones parallel to the axes of symmetry are unlike (except rarely 30°, and vary with the species. The orientation is best obtained by reference to the angles, and on this basis the important species may be tabulated as follows:

1. **With one direction of cleavage which bisects prominent angles, for example:** [illegible] 30° 26′; sillimanite, 91° 45′; goethite, 94° 52′; manganite, 99° 40′; brochantite, 103° 32′; atacamite, 113° 03′; staurolite, 129° 20′. Topaz, with one direction of cleavage, has prominent angles 124° 17′ and 90° 11′, not bisected by the cleavage.

2. **Crystals with two directions of cleavage or more than two in one zone, and known angles between faces parallel to two such directions:** columbite and chrysoberyl, 90°; andalusite, 90° 48′; natrolite, 91° 15′; enargite, 97° 53′; calamine, 103° 51′; [illegible]pyrite, 112° 27′; cerussite, 117° 14′; strontianite, 117° 19′; aragonite, 118° 12′; [illegible]ite, 119° 35′.

3. **Crystals with three or more directions of cleavage not in one zone, and known angles between faces parallel to such directions:** anhydrite, 90°; barite and 101° 38′; anglesite, 90° and 103° 44′; celestite, 90° and 104° 10′: stephanite, [illegible] and 107° 44′.

Monoclinic crystals. If a crystal shows one and only one axis of two-fold symmetry, or one and only one plane of symmetry, or both, it is a monoclinic crystal. Any face in the zone of the symmetry axis makes a 90° angle with the symmetry plane (or a face parallel to it). No other 90° angles occur. The cross-section of the zone of the symmetry axis is never rectangular, rarely hexagonal and usually markedly unsymmetrical.

Angles. No zone has a constant series of angles for each species. In this system the symmetry plane, the one symmetry axis and the cleavages, all assist in the orientation according to the following tabulation:

Easiest cleavage	Species	Angles in zone of symmetry axis	Angles bisected by symmetry plane
⊥ to symmetry plane	Colemanite	110° 9′, 111° 36′	107° 56′, 140° 12′, 126° 9′
	Gypsum		131° 30′, 143° 48′, 138° 40′
	Realgar		74° 26′, 132° 3′, 108° 2′
	Vivianite		
	Wolframite	118° 6′, 124° 18′, 117° 6′	100° 37′, 98° 6′, 117° 49′
∥ to symmetry plane	Azurite	135° 14′, 137° 10′, 132° 45′	99° 19′, 119° 13′, 90° 53′
	Borax	106° 35′	87°, 122° 33′, 96° 32′
	Cryolite	124° 58′, 124° 43′	91° 58′, 71° 32′
	Epidote	115° 23′, 128° 19′, 155° 11′	70° 4′, 70° 29′, 63° 5′
	Monazite	140° 48′, 87° 17′, 126° 29′	93° 26′
	Orthoclase	99° 42′, 129° 44′	118° 47′, 90° 7′
	Polybasite	90°	119° 58′
∠ between easiest cleavages bisected by plane of symmetry	Amphibole	130° 6′	124° 11′, 148° 28′
	Crocoite		93° 41′, 119° 10′
	Pyroxene	105° 50′, 148° 40′	87° 10′, 120° 49′, 131° 31′
	Spodumene	110° 20′	87°, 91° 26′
	Titanite	140° 43′, 159°	113° 31′, 136° 11′, 67° 57′
Cleavage	Datolite	90° 9′, 135°	115° 13′, 120° 56′, 115° 21′

micas and chlorites are usually pseudo-hexagonal.

Triclinic crystals. If the crystal shows no axes nor planes of symme is a triclinic crystal. There will be no right angles either between fa edges. The only corresponding faces will be opposite (parallel) faces. crystals of some of the most prominent triclinic minerals, however, approx in angles monoclinic crystals but are usually distinguishable by the occu of faces which have no symmetrically placed associates.

Angles. No angle will occur more than twice in any crystal. There are co tively few common triclinic species. The following table records a few of thei important angles:

Angles between the two easiest cleavages or the faces parallel to the cleavages		Other angles between com adjacent faces
The Plagioclases:		
Albite	93° 36′	127° 44′, 120° 46′
Anorthite	94° 10′	116° 3′, 98° 46′, 120° 31′
Labradorite	93° 56′	.....
Oligoclase	93° 28′	128° 3′, 98° 8′, 120° 54′
Amblygonite	104° 30′	120° 54′
Chalcanthite	123° 10′	110° 10′, 70° 22′, 103° 27
Cyanite	101° 30′	74° 16′, 131° 42′, 78° 58′
Rhodonite	87° 32′	107° 24′

Cleavage and its value as a test. In any crystal, whether with acteristic external form or not, the cohesion varies in different directions. U strain there is frequently a tendency to split or cleave perpendicular to directions of weakest cohesion *in definite* planes, which are always parall faces of simple crystals characteristic of the substance. In all crystals o same substance the same cleavages can be obtained. The number of direc of cleavage and the angles between the cleavage planes are, therefore, extre characteristic; moreover the cleavages serve to orientate the crystals in n cases. If the individual crystals are large enough, cleavage is obtained placing the edge of a knife or chisel upon the crystal and striking it a sh quick blow. If the individual crystals are very small the cleavage direct can usually be developed by crushing with pressure or a blow, and examining fragments with a hand glass.

In pyroxene, spodumene, corundum, magnetite, and some other species, some imens break easily in definite planes, while others do not. This is not true clea but a secondary phenomenon due to pressure, and is called "parting."

Cleavage and parting shapes may even be microscopically determined. To do sieve the crushed material through a 100-mesh screen upon a 120-mesh screen, particles remaining on the latter being collected on a clean paper.

A few fragments are placed in a drop of water or other liquid upon an object gla cover slip placed in position, and the preparation is examined.

Other tests dependent on crystalline structure. If the microscope is a able other tests may be applied to the crushed fragments, the best of which are: Ind of refraction (by the Becke or van der Kolk methods), absorption or pleochroism, ext tion angles, birefringence and elongation. A scheme for utilizing these tests was lished by A. J. Moses, in the *School of Mines Quarterly*, Vol. 34, July, 1913.

2. Important Physical Tests not Directly Dependent on Crystalli Structure

The most important of these tests or characters are Lustre, Color and Stre Hardness, and Specific Gravity.

Lustre. The lustre of a mineral is dependent upon its refractive power, its transparency, and its structure. It may be called the *kind* of brilliancy or shine of the mineral.

In determinative work minerals are broadly divided into Metallic and Non-metallic. Metallic lustre is the lustre of metals. It is exhibited only by opaque minerals, and these, *with the exception of the native metals, have a black or nearly black streak*. Opaque dark-colored minerals not distinctly non-metallic are said to be sub-metallic. Non-metallic lustre is exhibited by all transparent or translucent minerals. It may be vitreous or glassy, adamantine like unset diamond, resinous like sphalerite, pearly like mother of pearl, silky like fibrous serpentine, greasy like elaeolite, or waxy like chalcedony.

Hardness. The resistance of a *smooth* plane surface to abrasion is called hardness and is recorded in terms of the following scale:

1.0 Talc	6.0 Orthoclase	8.5 Chrysoberyl
2.0 Gypsum	7.0 Quartz	9.0 Sapphire
3.0 Calcite	7.5 Zircon	9.5 Carborundum
4.0 Fluorite	8.0 Topaz	10.0 Diamond
5.0 Apatite		

Approximations may be reached by use of finger nail (2½), copper coin (3) and knife (5½). Some smooth surface of the mineral to be tested is selected, and with a point of the standard is pressed and moved back and forth several times one-eighth of an inch or less. If the mineral is scratched it is softer than the standard. Two minerals of equal hardness will scratch each other. Pulverulent or splintery minerals are "broken down" by the test and yield an apparent hardness often much lower than the true hardness. Rough surfaces also yield doubtful results.

Color and streak. The color of minerals of metallic lustre and the color of the powder, or streak, when not white, are very much used in sight recognition. Minerals with non-metallic lustre often vary greatly in color. The color must safely obtained on a fresh surface. The streak is usually obtained by rubbing the mineral on a smooth but not glazed white or black surface, such as that of porcelain "streak plate" or a piece of touchstone (black quartz). The excess of powder should be brushed away and the thin adhering layer considered.

Specific gravity. The specific gravity of a substance is equal to its weight compared by the weight of an equal volume of distilled water at 4° C. Ordinary room temperature is used. Pure compact material is needed. The most accurate results are obtained by a delicate chemical balance, but for determinative purposes the following are more rapid and sufficiently accurate.

The **Jolly balance.** Two scale pans are attached, one below the other, to a spiral spring parallel to which is a mirror with a graduated scale. The lower scale pan is kept immersed in distilled water. The coincidence of a bead on the wire and its image in the mirror give:

A = Reading with nothing in either scale pan.
B = " " mineral in upper scale pan.
C = " " same fragment in lower scale pan.

$$\text{Sp. Gr.} = (B - A) \div (B - C)$$

The **Westphal balance.** More accurate results are obtained by substituting for the thermometer float of a Westphal balance a double scale pan, the lower pan of which is immersed in distilled water.

A = Weight needed to balance apparatus.
B = " " " " " with mineral in upper scale pan.
C = " " " " " " " lower scale pan.

$$\text{Sp. Gr.} = (A - B) \div (C - B)$$

Heavy liquids. If a fragment of a mineral is floating in a liquid of higher gravity and a diluent is stirred in, drop by drop, until the fragment if pushed do neither sink nor rise but stay where pushed, the specific gravity of the liquid a mined by a Westphal balance will be the specific gravity of the mineral. The liquids most used are: Methylene iodide (3.32); diluent, benzol. Bromoform diluent, xylol or benzol. Solution of mercuric iodide and potassic iodide (3.2); water.

4. Testing with the Blowpipe

Apparatus. The *essential* pieces of apparatus for all the tests given a

1. Either a gas blowpipe, or some form of burner for gas or heavy oil plain blowpipe.
2. Platinum wire about 0.25 mm diameter. Six inches of it will mal wires. A holder is needed.
3. Platinum-pointed forceps.
4. Charcoal in convenient sizes and with smooth surfaces (say 4 by 1 by
5. Tubes of hard glass about 3 by 5/16 in, closed at one end.
6. Pocket lens of good quality.
7. Simple goniometer.
8. Merwin Color Screen (G. M. Flint, Cambridge, Mass.).

For the other apparatus considerable latitude is possible and substitut be improvised for the regular stock article. The needed list would be: glasses, bottles (1 oz) for reagents, hammer, anvil, and magnet.

About ten reagents are used, the principal being borax, salt of phosp sodic carbonate, potassic bisulphate, cobaltic nitrate, and hydrochloric Two others are needed in preparing the bismuth flux and there will be n occasionally metallic tin and nitric or sulphuric acid.

A continuous blowpipe blast is obtained by distending the cheeks and the mouth as an air reservoir, breathing regularly through the nose and time to time admitting more air from the lungs through the throat mouth.

Any luminous flame may be used and, by regulating the relative amou air and flame, may be "blown" as a clear blue flame or a yellow flame, b which owe their color to incomplete combustion (CO or C) and therefore t *reduce*, that is, to take oxygen from substances placed therein. Hereafte flame is designated by the letters R.F. A practically non-luminous co envelope surrounds the blue flame and less distinctly the yellow flame. I there is an excess of oxygen and it therefore tends to *oxidize* substances therein. Hereafter this flame is designated by the letters O.F.

Fusion or fusibility. The ease of fusibility and the phenomena c fusion are convenient tests. The hottest portion of the flame is just b the tip of the blue flame. Some substances, noticeably certain iron ores, are infusible in the oxidizing flame are fusible in the reducing flame.

The test is most safely made by first heating on charcoal a fragment substance the size of a pin's head, to prove presence or absence of volat easily-reducible elements, which are likely to alloy with platinum. If the present the fusion test must be limited to the test on charcoal. If red metals or volatile constituents are absent, a small sharp-edged fragme heated in the platinum forceps, at the tip of the blue flame, directing the upon the point. Fragments long enough to project beyond the platinum sl be used and it is always well to examine the splinter with a magnifying before and after heating. *Fragments for comparison must be approximat same size and shape.*

The degree of fusibility is stated either in terms of a scale of fusibility, suggested by Kerl, or more simply as easily fusible, fusible, fusible with difficulty, or infusible:

Easily fusible:	1.	*Stibnite*, coarse splinters fuse in a candle flame.
	2.	*Chalcopyrite*, Small fragments fuse in the Bunsen burner flame.
Fusible:	3.	*Garnet* (*almandite*), coarse splinters easily fuse before the blowpipe. Not fusible in Bunsen burner.
	4.	*Actinolite*, fine splinters fuse easily before the blowpipe.
Fusible with difficulty:	5.	*Orthoclase*, fused only in fine splinters or on thin edges before the blowpipe.
	6.	*Calamine*, finest edge only rounded in hottest part of flame.
Infusible:	7.	*Quartz*, infusible, retaining the edge in all its sharpness.

The result of the fusion may be a glass or slag, which is clear and transparent, or white opaque, or of some color, or filled with bubbles; during the fusion there may be a slight intumescence, or a swelling and splitting (exfoliation). In certain instances the original form may change without fusion, or the substance may take fire and burn, or a gas may follow the loss of some volatile constituent.

Solubility. Acids, especially dilute (1 : 1) hydrochloric acid, are used not only to determine composition but also to determine the ease or degree of solubility. This test fails only from carelessness. The substance must be powdered as nearly pure as possible, finely ground and added to the acid in successive small quantities. A clear solution should be aimed at, acid being added only as it is needed until everything has dissolved. If complete solution cannot be obtained, the liquid must be filtered and the clear filtrate slowly and partially evaporated until separation commences. If doubt exists as to solubility the liquid *must be evaporated to dryness*, a residue proving solution to have taken place. Solubility may be accompanied by effervescence with or without odor of the acid, or only on heating. The evaporation may be difficult and incomplete, there may be separation of a perfect jelly, or of separate lumps of jelly, of powder, or of crystals. The solution may be of a characteristic color.

Testing for chemical components. The tests used are described in place in the determinative tables following Art 10. The manipulations and precautions are briefly as follows:

1. **Testing in closed tubes.** A narrow tube of hard glass, about 3 in by 5/16 in and closed at one end, is best. Enough of the substance is slid down a narrow strip of paper, which is inserted in the tube, to fill it to the height of about ¼ in; the paper is withdrawn and the inclined tube heated gradually at the lower end to a red heat. Soda or other reagents are sometimes mixed with the substance. The results may be: evolution of odorous or non-odorous vapors, sublimates of various colors, decrepitation, incandescence, fusion, charring, change of color, and magnetization.

2. **Testing on charcoal.** A shallow cavity, to prevent the substance from slipping, near one end of the charcoal, and a small fragment of the mineral is placed in it. The charcoal is held in the left hand, the surface tipped at about 120° to the direction in which the flame is blown, and a gentle O.F. is blown on the substance. If no sublimate forms the heat is increased, still keeping the flame oxidizing. Another fragment is treated in the R.F., the substance being kept covered for several minutes with the yellow flame.

The sublimates, their color, position on the charcoal, ease of removal by heating in the O.F. or R.F., and the colors imparted to the flame are all noted. Chemical changes may be indicated by reduced metal, magnetic residues, alkalinity, etc.

3. **Testing with soda on charcoal.** Sodic carbonate ("Soda"), heated on charcoal acts as a flux; it also exerts a reducing action, attributed to the formation of sodic oxide, nascent sodium, and carbon monoxide. It combines with many substances, forming both fusible and infusible compounds. The most satisfactory general method

is to mix one part of the substance to be tested with three parts of moistened soda little borax, and treat with a good R.F. on charcoal until everything that can be ab has disappeared.

IV. Testing with bismuth flux on charcoal and on plaster tablets. limates of brilliantly colored iodides and sulpho-iodides are obtained if bismut (two parts sulphur, one part potassium iodide, and one part acid potassium sulph mixed with certain powdered minerals, placed on charcoal, or a plaster tablet, and l gently. The larger series of tests are obtained on plaster, the sublimates differ position and to some extent in color from those obtained on charcoal. Plaster t are prepared by spreading a thick paste of plaster of Paris and water upon a sh oiled glass, and smoothing to a uniform thickness (¼ in to ½ in). While still so paste is cut with a knife into uniform slabs, 4 in by 1½ in. It is then dried, after the tablets are easily detached from the glass.

V. Flame coloration. A number of minerals when heated color the flame, so a gentle heat, some only at the highest heat attainable. Repeated dipping of the m in hydrochloric acid usually assists by forming volatile chlorides. A good meth cover all cases is as follows: Arrange a black background, such as a piece of cha powder the substance finely, flatten the end of a clean platinum wire and dip it in acid, then in the powder, and hold it first just touching the flame near the blowpip then at the tip of the blue flame; again dip in the acid and again heat as before.

Concentrated sulphuric acid, and also a paste made of water, 4½ parts acid potas sulphate and 1 part of calcium fluoride, are also used to release certain flame-col constituents, especially boron, phosphorus and lithium.

Red flames of calcium, strontium, lithium, and the violet flames of potassium i presence of sodium, are most conveniently studied by Merwin's Color Scale (*Sc* Vol. 30, p. 571), consisting of three colored strips of celluloid; No 1, blue, No 2, lapping blue and violet, No 3, violet. These absorb different portions of the spec as follows:

	No 1	No 2	No 3
Sodium	Absorbed	Absorbed	Absorbed
Potassium	Blue-violet	{ Violet and { Violet-red	{ Violet and { Violet-red
Calcium	Greenish yellow	Absorbed	Faint crim
Strontium or lithium	Absorbed	Absorbed	Crimson

These elements are still more exactly distinguished by use of a small pocket spe scope. The mineral is moistened with hydrochloric acid and brought on a plati wire into the non-luminous flame of the Bunsen burner. This is viewed through spectroscope and bright lines are seen. The yellow sodium line is almost invari present and the position of the other lines is best fixed by their situation relative to bright yellow line.

VI. Bead tests with borax and with salt of phosphorus. The oxides of cer elements dissolve in borax and salt of phosphorus and impart characteristic colors to mass, which may differ when hot and cold and according to the degree of oxidatio reduction. Preliminary to bead tests, sulphides, arsenides, arsenates, etc., may be verted into oxides by treating in a shallow cavity on charcoal at a dull red heat; first a feeble oxidizing flame, then a feeble reducing flame, then again an oxidizing flame, so on as long as odors or fumes are noticeable.

To make a bead: Make a loop in platinum wire by bending it around a pencil p so that the end meets but does not cross the straight part. Heat the loop, dip it into flux, and fuse to a clear bead the portion that adheres. Add more flux until the bea of full rounded shape. With salt of phosphorus the bead should be held a little ab the flame so that the ascending hot gases will help to retain the flux upon the w Touch the warm bead to the substance, place it in the O.F., and treat until clear. N the colors, hot and cold. Then treat in the R.F. and note colors as before.

Fusing. Some substances heated with a strong flame will give clear glasses until ...ed; but, if heated slowly and gently or intermittently, will yield opaque or enamel... beads before saturation.

Testing with cobalt solution. Certain substances become colored, when ...ated with a solution of cobalt nitrate in ten parts of water and then heated to a ... test. The test is usually made on charcoal. Certain other substances yield colors ... only heated, cooled, and then moistened with the cobalt solution without reheating. ... minerals boiled with cobalt solution are colored thereby.

OCCURRENCE AND ASSOCIATION OF MINERALS

5. Minerals of Rocks and Veins

Associates. Most minerals occur in more than one class of rock or mineral ...t, and therefore with different groups of associates. The most probable ...ates of any mineral in any particular occurrence are: 1. The great minerals ... form of occurrence. 2. Minerals containing some prominent element ...ments of the given mineral. In the following lists, which include the rock-...ing minerals and the minerals of economic importance, the species in italics ... relatively rare.

Minerals of the igneous rocks. These minerals in general have either sep...ted from a fusion solution or "magma" (each separating whenever for the ...ing temperature and pressure the magma is supersaturated with it), or ... have formed later, as secondary minerals, by the decomposition or alter... of the primary minerals. It is estimated that they constitute 95% of ... known crust of the earth.

Principal primary minerals of igneous rocks. Albite, anorthite, amphi...e (hornblende), biotite, chrysolite (olivine), enstatite, hypersthene, labra...ite, leucite, muscovite, nephelite (elaeolite) oligoclase, orthoclase, pyroxene ...ite), quartz, sodalite.

Minor primary minerals of igneous rocks. *Analcite*, apatite, *chalco...ite, chrysoberyl*, chromite, *cinnabar*, corundum, *epidote, garnet* (almandite, ...andite, pyrope), *goethite, gold, graphite*, hematite, ilmenite, *lepidolite*, mag...ite, *millerite, molybdenite*, monazite, pyrite, pyroxene (diopside), pyrrhotite, ...ile.

Secondary minerals in igneous rocks. *Albite*, alunite, analcite, apophyllite, ...ite, *azurite*, *barite*, calcite, chabazite, chalcedony, *chalcanthite, chalcopyrite*, chlo...ite *chrysocolla*, copper, datolite, epidote, kaolin, lepidolite, limonite, magnetite, *mala...ite*, muscovite, natrolite, opal, *pyrargyrite*, quartz, serpentine, siderite, *sphalerite*, ...ite, talc, *tetrahedrite, turquois*, wernerite.

Minerals of pegmatite veins. Vein-like portions of granites or other igneous rocks ... which the minerals of the rock are found in much larger crystals and in which many other minerals occur not noticed in the adjoining rocks.

Albite, *amblygonite*, apatite, beryl, biotite, *cassiterite, chabasite, chlorite, chrysoberyl*, ...ite, cryolite, *diamond, galenite, garnet* (almandite and spessartite), graphite, lepi...ite, magnetite, microcline, *molybdenite, monazite*, muscovite, nephelite, orthoclase, ...ite, *pyrrhotite*, quartz, spodumene, topaz, tourmaline, uraninite, zircon.

Minerals of ore veins. For convenience these have been listed under two headings: Minerals in zone of weathering or oxidation, and minerals of unoxidized zone. **In zone of oxidation.** Anglesite, azurite, brochantite, cala...ite, celestite, cerargyrite, cerussite, *chalcanthite*, chrysocolla, copper, crocoite, ...rite, embolite, erythrite, goethite, gold, iodyrite, limonite, malachite, manga-

nite, mimetite, pyromorphite, rhodochrosite, siderite, silver, **smithsonite**, *tianite*, *sulphur*, vanadinite, *vivianite*, wulfenite. **In unoxidized zone.** mony, argentite, *arsenic*, arsenopyrite, barite, bornite, braunite, **calcite**, c erite, chalcocite, chalcopyrite, cobaltite, copper, dolomite, fluorite, **gal** gold, graphite, jamesonite, linnæite, marcasite, millerite, niccolite, **orpi** orthoclase, pentlandite, proustite, pyrargyrite, pyrite, pyrrhotite, **quartz**, gar, smaltite, sphalerite, stannite, stephanite, stibnite, sylvanite, **tetrahe** uraninite.

Minerals of tin veins. Albite, amblygonite, apatite, arsenopyrite, muth, calcite, cassiterite, chlorite, columbite, fluorite, *galenite*, kaolin, **lepid** *molybdenite*, pyrite, pyroxene, quartz, scheelite, wernerite, wolframite.

Minerals of apatite veins. Albite, amphibole, apatite, biotite, ca *enstatite*, hematite, ilmenite, magnetite, oligoclase, pyrite, quartz, rutile, tita tourmaline, wernerite.

Minerals due to volcanic exhalations. Alunite, sassolite, sulphur, and *relat* small quantities of other species, as amphibole, hematite, sal-ammoniac, etc., occur a result of gases given off during volcanic action.

6. Minerals Found in Saline Residues

These exist as sediments precipitated from solution in natural waters, spr rivers, marshes, lakes, seas, and oceans.

From springs. Alunogen, aragonite, barite, bauxite (?), calcite, celestite, chalced cinnabar, fluorite, hydrozincite, kalinite, limonite, pyrite, sassolite, siderite, sulphur

From soda and borax lakes and lagoons. Anhydrite, calcite, borax, cele *cerargyrite*, colemanite, dolomite, *embolite*, *gold*, gypsum, halite, mirabilite, sass *soda nitre*, *sulphur*, *trona*, ulexite.

From oceans, seas, lakes, and marshes. Apatite, anhydrite, bauxite, bora *calcite*, carnallite, *celestite*, *cerargyrite*, *dolomite*, *epsomite*, gypsum, halite, kainite, kies limonite, siderite, wad.

Local saline residues (often incrustations or efflorescences). Alunite, aluno chalcanthite, copiapite, epsomite, kalinite, mirabilite.

7. Minerals in Gravels, Sands, Clays, and Marls

Minerals common to all. Biotite, calcite, chlorite, *garnet*, hematite, kaoli limonite, *magnetite*, muscovite, orthoclase, plagioclase, pyrite, *pyrophyllite*, *pyrox* rutile, siderite, titanite, *tourmaline*.

Gem minerals and ores in gravels and sands. Cassiterite, chrysoberyl, chryso corundum, diamond, gold, ilmenite, monazite, platinum, spinel, tourmaline, **topaz**, zir

Minor minerals in gravels and sands. *Amphibole*, *andalusite*, apatite, cyan *dolomite*, enstatite, epidote, *hypersthene*, *microcline*, sepiolite, serpentine, *sillimanite*.

Ores in clays. Galenite, limonite, manganite, psilomelane, pyrolusite, wad.

Minor minerals in clays and marls. Amphibole, aragonite, barite, *celestite*, g sum, halloysite, *orpiment*, realgar, strontianite, *vivianite*.

Minerals in sandstones. Chiefly quartz, orthoclase, plagioclase, limonite, mus vite. *Minor Minerals* are *carnotite*, *galenite*, *gold*, *marcasite*, *manganite*, *pyrite*, *py lusite*, *siderite*, *sphalerite*.

Minerals in sedimentary limestone. Aragonite, calcite, dolomite, fluorite, galen limonite (bog ore), *nitre*, opal (diatomaceous earth), *siderite*, *soda nitre*, sulphur, sphaleri

In serpentine and soapstones. *Amphibole*, *aragonite*, *arsenopyrite*, calcite, ch rite, chromite, chrysolite, cinnabar, diamond, dolomite, enstatite, epidote, garn (pyrope), garnierite, ilmenite, magnesite, magnetite, phlogopite, *platinum*, *pyroxe* pyrophyllite, quartz, *sepiolite*, serpentine, talc.

8. Contact Minerals

...e an igneous rock penetrates a preëxisting rock the heat, pressure, and ...d vapors frequently produce new minerals at and near the surface of ...

...ntacts with limestone. Amphibole (tremolite), anorthite, biotite, bor... ...rodite, corundum, *danburite*, *enstatite*, epidote, *fluorite*, garnet ...ar and andradite), graphite, *lazurite*, molybdenite, phlogopite, pyrite, ... (diopside), *scheelite*, spinel, tourmaline, *vesuvianite*, wernerite, wollas...

...ntacts with silicate rocks (clay, shale, slate, or crystalline schists). ... (hornblende), andalusite (chiastolite), biotite, chlorite, corundum, ... epidote, garnet, ilmenite, magnetite, pyroxene (augite), quartz, rutile, ...te, spinel, staurolite, titanite, tourmaline, topaz, wernerite, zircon.

Minerals of Metamorphic Rocks

...e minerals of the metamorphic rocks include many species of the ... rocks, and many species already listed under contact minerals. A ... list follows: In *Crystalline Limestones, and Dolomites:* amphibole ..., apatite, aragonite, calcite, *chondrodite*, corundum, dolomite, frank... *molybdenite*, phlogopite, pyroxene, pyrrhotite, rhodonite, serpentine, ...nite, spinel, *talc*, willemite, zincite, zircon. In *Gneisses and Schists:* ...tact minerals of the second list (contacts with silicate rocks). Also ...te, apatite, beryl, biotite, calcite, chalcopyrite, chrysoberyl, *datolite*, ..., *fibrolite*, graphite, hematite, molybdenite, monazite, muscovite, ortho... ...oclase, pyrite, pyrophyllite, pyrrhotite, talc, *tetrahedrite*, vesuvianite, ...

THE USES OF MINERALS

...is list includes only the principal uses of the minerals as such, and their ... as the material from which other substances are directly extracted or ...ufactured. The secondary products derived from these primary products ... not mentioned.

9. Uses of Minerals in Their Natural State

Abrasives. Quartz, garnet, opal (tripolite and diatomaceous earth), corundum and ... diamond (bort), orthoclase. Leucite and alunite rocks have been used as mill...

Building stones. Quartz, orthoclase, plagioclase, muscovite, biotite, pyroxene and ... in varying proportions, forming igneous rocks commercially known as granite ...; talc and pyrophyllite (soapstones), serpentines, calcite and dolomite (lime... and marbles), quartz (sandstone).

Electrical insulators. Muscovite, phlogopite, calcite (marble).

Fertilizers. Carnallite and kainite for potash; soda nitre for nitrogen; gypsum and ... lime; apatite (phosphate rock) for phosphoric acid. Muscovite and biotite as ...ers of moisture.

Fluxes. Calcite, fluorite, borax, pyrolusite.

Glass. Chiefly quartz (sand and sandstone) and calcite (limestone); to a less extent ...clase, plagioclase, cryolite, and pyrolusite.

Lubricants. Graphite, talc, muscovite.

Paints and pigments. Hematite and limonite as "metallic paint;" the same min... associated with clay, "ocher." Calcite (chalk) as "whiting;" wad, barite, gypsum, ...a, muscovite, talc, kaolin, quartz, magnesite, azurite, graphite, asphaltum.

Paper manufacture. Talc (fibrous), gypsum (selenite), as constituents of Barite, calcite, kaolin, magnesite, bauxite, muscovite, for weight and glaze.

Porcelain, pottery, etc. Kaolin and other clays, quartz, orthoclase, albite gypsum.

Precious stones. Diamond, beryl, emerald, corundum (sapphire and ruby), beryl (alexandrite), garnet (demantoid), spinel (ruby spinel). **Semi-precious** Other varieties of beryl, corundum, chrysoberyl, spinel, and garnet. **Also opal** olite (peridot), quartz (amethyst and yellow), topaz, tourmaline, turquoise, spodumene (kunzite, hiddenite), orthoclase (moonstone). **Ornamental stones.** chalcedony (onyx, carnelian, sard, agate, etc.), quartz (rose, cat's eye, ave smoky, etc.), orthoclase (amazon stone), plagioclase (labradorite and sunstone phibole (jade), lazurite (lapis lazuli), malachite, azurite, calamine, smithsonite, chr fluorite, gypsum (satin spar), serpentine, hematite, pyrite, rhodonite, talc. Oc faceted stones are cut from apatite, andalusite, cassiterite, chondrodite, cyanite, p (diopside), enstatite, epidote, prehnite, staurolite, titanite and vesuvianite.

Refractory materials and heat insulators. Asbestos, bauxite, chromite, d graphite, ilmenite, kaolin, magnesite, muscovite, opal (diatomaceous earth), ser (chrysotile), quartz, pyrophyllite and talc (soapstone).

Rubber manufacture. Sulphur, stibnite, barite, calcite.

Soap and washing powders, toilet articles. Borax, opal (diatomaceous talc, quartz, magnesite, orthoclase.

Sundries. *Coloring or decolorising:* pyrolusite, psilomelane, rutile. *Cond* halite. *Explosives:* nitre, sulphur. *Filters:* opal (tripolite). *Enamels:* fluorite, *Matches:* stibnite, sulphur. *Optical:* quartz, calcite, fluorite, gypsum, mus *Pencils:* graphite, talc, pyrophyllite. *Pipes:* sepiolite (meerschaum), succinite (a

10. Products Extracted or Manufactured Directly from Mine

Aluminum from bauxite, possibly gibbsite, with cryolite as flux.
Alundum (Al_2O_3) from bauxite.
Aluminium sulphate and alum from alunite, cryolite, bauxite, kaolin.
Antimony from stibnite and its alteration products and lead ores carrying *antim*
Arsenic from arsenopyrite and sometimes from smaltite, cobaltite, enargite, etc.
Barium hydroxide and barium sulphide from barite.
Bismuth from native bismuth, bismutite, and bismite.
Borax and boric acid, from colemanite, ulexite, borax, and sassolite.
Bromine from halite (salt brine).
Cadmium from sphalerite and smithsonite containing greenockite.
Calcium oxide (lime) from calcite (limestone).
Calcium sulphate (hemi-hydrate) or plaster from gypsum.
Calcium superphosphate from apatite.
Cements from calcite and clays.
Carbonic acid from magnesite and calcite.
Chlorine from hydrochloric acid and pyrolusite, the former being derived from ha
Chromium alloys, especially ferrochrome from chromite.
Cobalt oxide and cobalt arsenate (saffre) from smaltite, cobaltite, and cobaltif limonite.
Copper principally from chalcopyrite and bornite, native copper, cuprite, mala and azurite, though chalcocite, enargite, tetrahedrite, atacamite, brochantite, cha thite, and chrysocolla are all sources of copper in certain districts. In addition to the iron sulphides often carry copper which is extracted after burning for sulphuric
Copper sulphate from chalcopyrite.
Gold from gold and the gold tellurides (sylvanite, calaverite, petzite), from silver copper ores and from the minerals pyrite, arsenopyrite and pyrrhotite, and spha and other sulphides or tellurides.
Hydrochloric acid from halite.
Hydrofluoric acid from fluorite and cryolite.
Iodine from sodium iodate obtained from soda nitre.
Iridium from iridosmine.

... hematite, limonite, magnetite, and siderite, goethite, and turgite (commer-
... with limonite), some ilmenite, and rarely residues from the roasting of
...

... (ferrous) or "copperas" from pyrite and chalcopyrite.
... *alloy* from franklinite and certain manganiferous hematites and sider-
... pyrolusite, psilomelane, manganite and other manganese oxides.
... from galenite and cerussite. Anglesite and pyromorphite sometimes occur
...

... (sublimed white lead and blue lead) from galenite.
... *carbonate* from spodumene, lepidolite, amblygonite.
... from carnallite.
... *carbonate* from dolomite. Basic carbonate from kieserite.
... *oxide* from magnesite, and indirectly kieserite.
... *chloride* from carnallite.
... *sulphate* (epsom salts) from kieserite and less extensively from magnesite
...

... *alloys* from pyrolusite, psilomelane and braunite, or with intermixed rhodo-
... and rhodonite.
... salts from pyrolusite.
... from cinnabar.
... *and ammonic molybdate* from molybdenite.
... from pentlandite, garnierite, nickeliferous pyrrhotite, and to a less extent
... niccolite and the cobalt minerals, cobaltite and linnæite.
... acid from soda-nitre and nitre.
... from copper ores and platinum.
... from an impure calcium phosphate (sombrerite), or from bone ash.
... from native platinum and sperrylite, and from some gold and copper ores.
... from carnallite.
... *dichromate* from chromite.
... *sulphate* from kainite.
... *nitrate* from soda nitre and carnallite.
... *chloride* from uraninite, carnotite, and autunite.
... from platinum.
... from sulphur, chalcopyrite, and pyrite.
... *carbide* (carborundum) from quartz and coke.
... *alloys* (ferro-silicon) from quartz.
... from native silver, argentite, cerargyrite, embolite, proustite, pyrargyrite, and less
... , hessite, polybasite, and iodyrite. Included in other minerals, notably, galen-
... cerussite, but also in copper ores, manganese ores and with gold in pyrite and arsen-
...

... *borate* (borax) from colemanite, ulexite, sassolite, and native borax.
... *stannate* from cassiterite.
... *sulphate* (salt-cake) from halite, and from this, caustic soda, carbonate, bicar-
... etc.
... *nitrate and chloride* from strontianite.
... *acid, sulphurous acid*, from native sulphur, pyrite, marcasite, chalcopyrite,
... pyrrhotite, and other sulphide ores.
... from columbite.
... *nitrate and thorium oxide* from monazite, thorite, thorianite.
... *and sodium stannate* from cassiterite.
... *and ferro-titanium* from ilmenite.
... *carbide* from rutile.
... *ferro-tungsten*, from wolframite and scheelite.
... *of soda* from wolframite.
... *yellow or sodium diuranate* from uraninite, carnotite.
... *and ferro-vanadium* from carnotite, patronite, roscoelite, vanadinite, descloi-
...

... *oxide* from mottramite.
... *"zinc dust," and zinc oxide* from sphalerite, smithsonite, and calamine; and, in
... Jersey, willemite and zincite.
... *sulphate* from sphalerite.
... *oxide* from zircon.

DESCRIPTIVE AND DETERMINATIV TABLES

Rare species without economic value are omitted from these tal found and tested, the result would be a failure to identify. Their i would enormously increase the complexity of the tables and somewhat the difficulty of any determination.

In view of the limited space the species are described only in the tab the accompanying index will enable the user to find a brief description species.

(For example, Scheelite. A reference to VII, 4, will give compositio talline system, hardness, specific gravity, colors, solubility, flame colc behavior with fluxes and general appearance.)

The uses and occurrence of minerals are summarized in separate tabl using the tables the customary precautions are understood to be taken:

1. Tests must be made upon homogeneous materials, and lustres and observed on fresh fractures.

2. Classifying tests must be decided; not weak, nor indefinite. If cided, the species on both sides of the dividing line must be considered.

3. Hardness tests should be assumed to be within say one half; tha determination H = 5 should for safety be taken as 4.5 to 5.5.

As shown by the accompanying key, the principal subdivision is be metallic and non-metallic lustre. The blowpipe test is made subordina minerals of metallic lustre and minerals of non-metallic lustre with c streaks; but, for minerals of non-metallic lustre with white streaks, expe has proved that either the blowpipe or the microscope lead to a determi with less repetition than such qualities as color and hardness.

A novel feature of the tables is the "scheme within a scheme," by whi order of testing may be varied. For instance, in Table VI the arrangem by blowpipe tests in order of hardness, but the parallel columns permit to be used as the classifying test; that is, the order of testing may be colo hardness or blowpipe test and hardness.

Similarly in Table III, the arrangement of the metallic white and gray erals is by streak and hardness, but the parallel columns permit the behavi charcoal in oxidizing and reducing flame to be used as the classifying test; th the order of testing may be color, streak and hardness, or color and beh on charcoal.

Chemical symbols are used only for the formulas of the species and fo common solvents, HCl, H_2SO_4, HNO_3, KOH, etc. Aside from these a abbreviations are used, the principal being:

Systems of crystallization are indicated by the letters: I (Isometric), T (ragonal), O (Orthorhombic), M (Monoclinic), Tri (Triclinic), H (Hexagon

Terms in blowpipe tests. Soda for sodic carbonate, S. Ph. for sa phosphorus, O. F. and R. F. for oxidizing and reducing flame, Co. Sol. for co solution, coal for charcoal.

The + sign in any column opposite any mineral indicates that the qu indicated is a character of that mineral.

TABLE I. *Minerals of Metallic or Sub-Metallic Lustre, Black or Nearly Blac Color* (including arbitrarily some dark-colored minerals of doubtful lust

1. With black or nearly black streak.
2. With streak not black.

TABLE II. *Minerals of Metallic Lustre, Tin White, Silver White, Lead Gray or Steel Grey in Color.*

With black streak.
With streak not black.

TABLE III. *Minerals of Metallic Lustre, Metallic Yellow, Bronze or Red in Color.*

With black streak.
With streak not black.

TABLE IV. *Minerals of Non-Metallic Lustre, with Decided Taste* (soluble in water).

When fused, powdered, moistened with concentrated H_2SO_4 and ignited on platinum wire, yield:

Flame yellow. No violet through blue glass.
Flame violet through blue glass.
Flame green.
Flame not colored.

TABLE V. *Minerals of Non-Metallic Lustre, Tasteless, with Colored Streak.*

Blue streak.
Green streak.
Yellow to yellowish brown streak.
Red to reddish-brown streak.
Orange streak.

TABLE VI. *Minerals of Non-Metallic Lustre, Tasteless, with White Streak, Yielding Reactions on Charcoal with Sodic Carbonate:*

Volatile fumes or sublimates.
No fumes or sublimates, but are reduced to metallic or magnetic particles.
No fumes, sublimates or reduced particles, but if moistened will stain silver.

TABLE VII. *Minerals of Non-Metallic Lustre, Tasteless, with White Streak, Yielding no Tests with Sodic Carbonate.*

A thin fragment heated in platinum forceps at tip of the blue flame is:

Fused easily (1 to 4) to a white, opaque glass, or enamel.
Fused easily (1 to 4) to a colorless glass.
Fused easily (1 to 4) to a colored glass.
Fused with difficulty (5 to 6), sometimes barely rounding the edges.
Infusible, but in powder is made deep blue by ignition with cobalt solution.
Infusible and is *not* made deep blue by ignition with cobalt solution.

A. WITH STREAK NOT BLACK

Sub-Metallic Lustre, Black or Nearly Black in Color

	Solubility	Heated in closed tube	Other tests	Appearance
	Sol. HNO_3. White residue	Subl. black hot, red cold	Decomposed by KOH. HCl produces orange ppt.	Veins or crusts with a brilliant adamantine lustre showing red tint in thin layers. Rare crystals. Streak purplish-red.
	Effervesces. Gives odor H_2S	No sublimate	Sublimate on coal made bright green by ignition with cobalt solution	Black and gray crystals and cleavable to fine-grained masses. Streak pale brown.
	Sol. HCl. (Evolves Cl)	Much water. A little oxygen	Borax O. F. amethystine	Crystals often grouped in bundles, rarely massive, granular or stalactitic. Streak dark brown.
	Soluble	Reddens. Yields much water	Often reacts for manganese and may give jelly residue	Cellular and pulverulent or as compact masses often radiated or stalactitic and with varnish-like surfaces. Never crystallised. Streak yellowish-brown.
	Soluble	Reddens. Yields water	Often reacts for manganese. (Soda bead O. F. bluish green)	Occurs massive but is best known as crystals, often flattened like scales, or needle-like, or in parallel position. These shade into feather-like and velvety crusts.
	Sol. HCl. (Evolves Cl)	.....	Borax O. F. amethystine	Granular masses occasionally in twinned pyramids. Streak chestnut brown.
	Partial	.....	Solutions become deep blue on addition of tin. Solution of S. Ph. bead in HCl best	Heavy monoclinic crystals and cleavable, bladed and granular masses. Streak brownish black.
	Partial	.....	Filtered solution boiled with tin becomes violet	Usually compact masses, often thin plates or imbedded grains or as sand. Rarely in tabular hexagonal crystals. Streak brownish red.

Metallic Yellow, Bronze or Red in Color

...ability	Heated in closed tube	Other tests	Appearance
HNO_3 ...ndue	Blackens	Magnetic globule is brittle with red fracture and ignited with HCl gives azure blue flame	Red bronze on fresh fracture. Tarnishes in blue, purple and black tints. Very brittle and usually massive.
...aqua ...gia	.....	Roasted colors borax O. F. red hot, brown cold	Brass colored in hair-like or needle crystals. Crusts made up of radiating needles.
... HNO_3 ...ndue	Darkens, may give yellow sublimate	Like bornite except gray "fracture"	Bright-yellow brassy masses and crystals, tarnishing in peacock colors.
.....	.....	Fused globule yellow on fracture. Borax O. F. reddish brown	Light bronze-yellow masses resembling pyrrhotite but not attracted by a steel magnet. Cleavage octahedral.
...rvescs ...der ...)	A little S	Slightly magnetic before fusion	Bronze-yellow masses, tarnishing brown. Powder attracted by a steel magnet.
...tal	Mirror sublimate	Borax and roasted material give blue, green, brown, successively as borax is changed	Pale copper-red masses sometimes enclosed in white metallic crust.
... HNO_3 ...ndue	Fusible sublimate red hot, yellow cold	Fused mass effervesces in HCl with odor H_2S	Pale brass-yellow cubes or other crystals, isolated or grouped in crusts or bounding a mass. Also massive globular, nodular stalactitic.
HNO_3 ...ndue	Fusible sublimate red hot, yellow cold	Like pyrite	Pale brass-yellow "spear," "cockscomb" and simple tabular crystals. Often radiated. Fresh fracture whiter than that of pyrite.
aqua ...gia	.....	The fused mass is yellow	Golden yellow to pale yellow nuggets, grains and scales or distorted crystals passing into wire, fern and leaf forms. Malleable. Streak golden yellow to pale yellow.
HNO_3 ...ued)	.....	Fused mass is red and ignited with HCl gives azure blue flame	Copper red, disseminated grains sheets and irregular masses or groups of extended and branching crystals. Malleable. Streak copper red and shining.

Table IV. Minerals of Non-Metallic

	Crystal system: name, composition, hardness and specific gravity	Taste	Heated on cha
FUSED, POWDERED, MOISTENED WITH CONC. H_2SO_4, AND IGNITED ON PLATINUM WIRE			
1. FLAME YELLOW. ABSORBED BY "COLOR SCREEN"	H. Soda nitre..... $NaNO_3$ H=1.5 to 2 G=2.2	Cooling	F.=1. Deflagr
	M. Mirabilite,..... $Na_2SO_4+10\,H_2O$ H=1.5 to 2 G=1.5	Bitter	Fuses and will silver

		There is efferves-cence	There is a residue of jelly	Simple solution
1. WITH BLUE STREAK	M. Vivianite $Fe_3(PO_4)_2+8H_2O$ H=1.5 to 2 G=2.6 to 2.7	.....	.....	+
	—. Chrysocolla $CuSiO_3 \cdot 2H_2O$ H=2 to 4 G=2 to 2.3	.....	.....	+ (Separatior of silica)
	M. Azurite $Cu_3(OH)_2(CO_3)_2$ H=3.5 to 4 G=3.8	+	.....	.....
	I. Lazurite $Na_4(NaS,Al)Al_2(SiO_4)_3$ H=5 to 5.5 G=2.6 to 2.9	+ (Odor H_2S)	+	.....
2. WITH GREEN STREAK	Chlorite Group H=1 to 2.5 G=2.6 to 2.9 (Micaceous dark-green minerals such as clinochlore $H_8Mg_5Al_2Si_3O_{18}$)	.....	.....	.....
	Garnierite $H_2(Ni \cdot Mg)SiO_4+H_2O$ H=2 to 3 G=2.3 to 2.8	.....	.....	+ (Separatior of silica)
	O. Atacamite $Cu_2(OH)_3Cl$ H=3 to 3.5 G=3.7 to 3.8	.....	.....	+ (Green)
	M. Malachite $Cu_2(OH)_2CO_3$ H=3.5 to 4 G=3.9 to 4	+	.....	.....
	O. Brochantite $CuSO \cdot 3Cu(OH)_2$ H=3.5 to 4 G=3.9	.....	.....	+
	Turquois $Al_2(OH)_3PO_4H_2O$ H=6 G=2.6 to 2.8	.....	.....	+

...ss, Tasteless and With Colored Streak

...ity ...ak	Heated in closed tube	Other tests	Appearance
...25 ...per)	Water. (Turns brown)	Momentary blue flame with H_2SO_4 (conc.). Yellow pt. with ammonic molybdate	Bluish-green to dark blue, often earthy and filling shells, horn, etc. Rarely as colorless or glassy crystals, gradually becoming blue.
...ble. ...kens)	Blackens. Yields water	.....	Enamel-like crusts, veins, or masses.
3 ...ack)	Blackens. Yields water	Emerald-green flame. Solutions blue with ammonia	Dark-blue glassy crystals, lighter blue crusts, velvety, dull or earthy masses.
35 ...ze)	Water. (Green glow)	Yellow flame	Deep-blue fine-grained masses usually spangled with pyrite and intermixed with other minerals.
...ored)	Much water	Milky solutions with concentrated H_2SO_4	Dark-green masses of coarse to very fine scales. Tabular and curiously twisted six-sided crystals and fan-shaped groups which cleave into thin soft pliable but not elastic plates. Also as a pigment in other minerals.
...ble. Mag- ...se)	Blackens. Yields water	Borax O. F. violet hot, brown cold	Dark emerald-green masses often cellular and very crumbly and paler-green masses and crusts. Lustre dull.
1 20 4 ...pper)	Acid water	Azure blue flame. White and red sublimates	Deep emerald-green, confused aggregates and slender prisms. Formerly found as a sand.
3 ...ack)	Blackens. Much water	Green flame, blue with HCl	Bright-green radiating fibres or crusts, often banded in shades of green, sometimes stalactitic. Also dull green and earthy. Rarely, slender crystals.
...per)	Water. May blacken. Acid at high temperature.	Green flame, blue with HCl. Fused with soda stains silver	Emerald-green needle crystals. Fibrous veins and crusts.
...ens)	Blackens. Yields water	Yellow ppt. as in vivianite. Green flame, blue with HCl	Sky-blue to green nearly opaque nodules or veins, with lustre of wax.

Soak, and Yielding Reactions on Charcoal With Sodic Carbonate

Solubility	Flame coloration	Heated in closed tube	Other tests	Appearance
Soluble	Blue	Yellow fusible. Sublimate brown hot	Takes fire and burns with odor SO_2	Bright translucent crystals and masses or powder with resinous or dull lustre.
Sol. with effervescence	.....	Water. Yellow hot	On coal R.F. heavy white subl. made bright green by ignition with cobalt solution	Chalk-like masses or crusts on other zinc minerals.
Volatile	Yellow green (Coal R. F.)	Fuses, partly sublimes	Volatile white subl. on coal	White silky minute crystals or radiating fibres.
Insoluble	.....	Decrepitates	Bright yellow subl. on coal with Bi flux	Simple crystals, often transparent and colorless. White brittle masses and compact granular masses of gray color from intermixed galenite.
Partial to green solution	.....	Darkens. Decrepitates	Like anglesite. Also solution, cooled, diluted boiled with tin is blue	Tabular square crystals of resinous lustre.
Sol. HNO_3 to yellow solution	.....	With $KHSO_4$ yellow to red hot, yellow cold	S. Ph. O. F. amber, R. F. green	Sharp hexagonal prisms, sometimes hollow. Also parallel groups and globular masses.
Sol. with effervescence in hot HCl. Crystals on cooling	.....	Turns yellow then red, cools yellow	Like anglesite	Twinned crystals or interlaced fibres or granular masses, often with galenite.
Sol. HNO_3	.....	.....	Like anglesite. Also fuses O. F. and on cooling has facets	Hexagonal prisms and tapering groups in parallel position. Also rounded and moss-like aggregations.

With White Streak and Yielding Reactions on Charcoal With Sodic Carbonate

Solubility	Flame coloration	Heated in closed tube	Other tests	Appearance
[illegible] with [illegible]	Emerald green	Blackens. Yields water	With soda on coal a copper button	Enamel-like crusts, veins or compact masses. Never crystals.
Slow effervescence in cold acid	.....	Black and magnetic	On coal becomes black and magnetic	Compact, fine-grained and cleavable masses and rhombohedral curved crystals. Cleavage angles 107°.
[illegible] Recrystallizes on evaporation	Yellowish red	Whitens. Yields water	.....	Soft, colorless or slightly tinted masses, which may be scaly, silky fibrous or compact or may be masses and crystals, cleaving in three directions to a rhombic plate of 66°.
Insoluble	Yellowish green	.....	.....	Granular, cleavable and fibrous. Crystals common. Cleaves in three directions to rhombic plates of 78½°.
Insoluble	Crimson	.....	.....	Colorless to white crystals and fibrous, lamellar and granular masses. Cleaves in three directions to rhombic plates of 76°.
Soluble [illegible] with $BaCl_2$	Yellowish red	.....	.....	Cleavable and fine-grained masses. Cleaves in three directions at 90°.
Mineral	Violet. (Color Screen)	Water at high heat	Blue by ignition with co. solution	Fibrous or lamellar or small cuboids, usually mixed with hard, siliceous material.
[illegible] with [illegible] and odor H_2S	Yellow	Water and green glow	Blue in fine powder	Fine-grained, usually spangled with pyrite and intermixed with other minerals.

With White Streak and Yielding No Tests with Sodic Carbonate

[illegible]	Flame coloration	Heated in closed tube	Other tests	Appearance
[illegible]	Yellow	.....	Blue if ignited with cobalt solution	Translucent masses and coarse hexagonal crystals with peculiar greasy lustre. More rarely highly modified small white crystals.
[illegible]	.....	.....	.....	Usually prismatic crystals with eight-sided cross-section and angles between alternate faces 90° or 87°. Cleavage angle of 87°.
[illegible]	.....	.....	.....	Fibrous and columnar, often radiating. Also crystals with cross-section, a rhomb of 124° or six-sided section. Cleavage at 124°.
[illegible]	.....	.....	.....	Masses and crystals with two easy cleavages, nearly but not exactly 90°. Often show parallel striations. Sometimes opalescent.
[illegible]	Yellow	.....	.....	Usually pure white, often granular with curved cleavage surfaces.
[illegible]	.....	.....	White ppt. with H_2SO_4	Highly modified glassy crystals or grayish-white larger crystals
[illegible]	Yellow	.....	.....	Broad cleavages. Good striations. Sometimes spangled (Sunstone).
[illegible]	.....	.....	.....	Good striations. Beautiful play of color.
[illegible]	Crimson	.....	Sprouts and becomes opaque during fusion	Coarse, flattened prisms with cleavage at 87°. Often separate in broad plates (bisecting cleavage angle). Often striated and etched or roughened.

and With White Streak and Yielding No Tests With Sodic Carbonate

[illegible]	Flame coloration	Heated in closed tube	Other tests	Appearance
[illegible] slowly	.....	May become yellow	S. Ph. O. F. slowly soluble. Undissolved portion milk white, R. F. violet	Wedge-shaped or tabular crystals, with adamantine lustre. Also massive. Easy cleavages give monoclinic shapes.
[illegible] nearly	.....	.....	.....	Usually eight-sided prisms with angles between alternate faces 90° and 87°. Cleavage angle 87°.
[illegible]	.....	.....	.....	Bladed non-terminated crystals, divergent fibres and granules.
[illegible] nearly	.....	.....	.....	Crystals six-sided cross-section, with angles 124° and 116°, also fibrous and compact masses. Sometimes with lustre of horn.
[illegible] [illegible]	.....	.....	After fusion attracted by magnet	Foliated aggregates sometimes with peculiar "Schiller" or pearly effect.
[illegible] with [illegible]	.....	.....	Borax, O. P. amethystine	Fine-grained or cleavable masses and disseminated grains, often coated with a black oxide. Sometimes in crystals.
[illegible] nearly	.....	Water at high heat	After fusion will gelatinize	A secondary mineral often with the original mineral as grains or needles. Less frequently in distinct crystals.
[illegible] nearly	.....	Water at high heat	After fusion will gelatinize	Square and octagonal prisms and radiated columnar or granular masses or compact resembling jade.
[illegible]	.....	.....	After fusion will gelatinize	Imbedded crystals, often nearly spherical or in druses and granular, lamellar and compact masses. Also found in alluvial material as rounded grains.

With White Streak and Yielding No Tests With Sodic Carbonate

	Flame coloration	Heated in closed tube	Other tests	Appearance
	Green with $KHSO_4$ - CaF_2	.....	After fusion will gelatinize	Prismatic crystals, the cross-section often showing a triangular prism. Often the color is different at opposite ends or centre and outer shell. Also radiating aggregates and in compact masses.
	.....	Water	Blue if ignited with cobalt solution	Radiated folia or fibres and compact masses. Smooth and soft like talc.
	.....	Water	Pink if ignited with cobalt solution	Foliated compact and fibrous masses with soapy feeling. The foliated talc cleaves into non-elastic plates.
	.....	Much water	.....	Masses of coarse to very fine scales. Tabular and curiously twisted six-sided crystals and fan-shaped groups which cleave into thin, soft pliable but not elastic plates. Also as a pigment in other minerals.
	.....	Much water	.....	
	.....	Water	Pink if ignited with cobalt solution	Soft, compact, smooth feeling masses of very light weight. Rarely fibrous.
	.....	Water at high heat	.....	Plates and masses of scales and crystals, often large and rough, with rhombic or hexagonal cross-section. Lustre pearly, cleavage very easy into thin elastic plates.
	.....	Water at high heat	.....	Scales or aggregates. Rarely large sheets or pseudo hexagonal crystals cleaving easily into thin elastic plates. Lustre pearly.
	.....	Water at high heat	.....	Rough prisms with hexagonal or rhombic sections. Also disseminated scales. Cleaves easily into thin elastic plates.

[illegible] White Streak and Yielding No Tests With Sodic Carbonate

[illegible]	Flame coloration	Heated in closed tube	Other tests	Appearance
[illegible]	.....	Water	Pink or brownish red if powder ignited with cobalt solution	Compact masses with little lustre and smooth somewhat greasy feel, often with veins of silky fibres or foliated.
[illegible]	Crimson	.....	Sprouts and glows intensely during fusion	Masses of parallel or radiating imperfect needle crystals. More rarely fine granular.
[illegible]	Pale red	.....	.....	Fibrous to compact masses. Rarely tabular crystals. Usually intermixed with calcite.
[illegible]	Pale red	.....	S. Ph. O. F. colorless to milk white. R. F. deep blue	Very heavy masses with resinous lustre. Square pyramids and drusy crusts.
[illegible]	Yellowish red. Momentary green with H_2SO_4	.....	Solution added to nitric sol. of ammonia molybdate gives bright yellow ppt.	Usually hexagonal prisms. Lustre of oiled glass, dull if altered. Also compact, dull, massive bone phosphate.
[illegible]	.....	.....	Like serpentine	Lamellar to fibrous masses, often with pearly lustre.
[illegible]	Violet (Color screen)	.....	.....	Masses and crystals which cleave in two directions at exactly 90°. Except in the variety microcline the surfaces resulting are not grooved. Sometimes opalescent.
[illegible]	Green with $KHSO_4$ CaF_2	.....	After fusion will gelatinize	Prismatic crystals, often showing a triangular prism. The color may differ at opposite ends or centre and outer shell. Also radiating aggregates and in compact masses.
[illegible]	.....	.....	Often becomes white on fusion	Hexagonal prisms, from mere threads to several feet in length. Sometimes also in columnar or granular masses.

...ble	Green with $KHSO_4$ CaF_2	.....	.....	Glassy hexagonal prisms differently faced at the two ends. Cross-section often suggests a triangle.
...ble	.....	.....	In powder is burned to CO_2	Crystals often rounded with lustre suggesting oiled glass, and cleavage in four directions at 70° 31′.

Table VIII.—Mineral Substances not easily Determinable by a Sche

The following mineral substances of economic importance have not been inc the determinative tables, some because they lack fixed characters, others beca characters are lost in those of their associated substances and others because th only in one known locality.

Amber, once the most prized of gems, now used sometimes in jewelry, oft mouthpiece for pipes, is a name given to those fossil resins which contain succ and were derived from a particular extinct species of pine. The amber of th Sea and the Sicilian amber are the most valued. Color, garnet red, reddish brownish, sometimes with bluish fluorescence. Lustre resinous, streak white, H 2.5. G = 1.096. Melts quietly at 125° to 150° C. and gives off a choking vap

Asphalts are rather indefinite mixtures of hydrocarbons and their oxidized p They vary from thick, highly viscous liquids to solids, are generally black in co pitch-like lustre, and burn easily with a pitchy odor. They are slightly heav water. Examples: the pitch lakes of Trinidad and of Bermudez, Venezuela; the of Barbados; the elastic elaterite of Derbyshire, England; the albertite of New wick, and the gilsonite of Utah. Sandstones and limestones impregnated with occur in many localities.

Carnotite, $2\ UO_3V_2O_5K_2O\ 3\ H_2O$ (?). A canary yellow, pulverulent mineral, in scales, filling the interstices of sandstone in several counties in Colorado. Rar pact and wax-like. It contains radium, and is an impure vanadate of uranium tassium, or uranium and lime, or both. Is a commercial source of radium, urani vanadium.

Clays are mixtures of mineral fragments, due to rock decay. They are usuall when wet, can be molded, and harden on heating. By analysis they are principal and alumina, with some iron oxide and small amounts of other elements. Mi cally they contain hydrous silicates of alumina, free quartz, and varying amounts other minerals. In origin they may have resulted from decay in place (residu or may have been transported by water, ice, or wind (sedimentary clays). T important clays are:

Kaolins. White-burning, residual clays, often not plastic, approaching kaol composition, but not necessarily composed chiefly of that mineral. They are t of white wares and porcelain, etc.

Ball clays. White-burning sedimentary clays. They are highly plastic added to kaolin to give plasticity.

Fire clays. Either sedimentary or residual clays, which stand high degrees without fusion. Composition very variable and apparently best with little fre lime, magnesia, or alkalis.

Stoneware clays. Clays sufficiently plastic and tough to be turned on a potter'

Terra-cotta clays. Usually buff-burning clays, with low shrinkage and dense character.

Sewer pipe and paving-brick clays. Vitrifiable, high in fluxes.

Brick clays. Low-grade clays, with considerable plasticity, which harden at paratively low temperature.

Slip clays. Melt at a comparatively low temperature and form a glaze.

Paper clays. White clays free from sand; used for mixing with pulp fibre.

Kieserite ($MgSO_4 + H_2O$) is the source of Epsom salts, and an important so magnesium oxide and basic carbonate (magnesia alba). It occurs at Stassfurt, I as about one-fifth of a layer 190 ft thick, chiefly halite and carnallite, and as one constituents of the overlying mixed salts. Exposed to the air it becomes ep After removal of associates there remains a mass slowly soluble in water and easily H = 3 to 3.5, G = 2.5. Rarely orthorhombic crystals.

Livingstonite ($HgSb_2S_4$). Found in Mexico at Huitzuco and Guadalcazar and said to be used as a source of mercury. It resembles stibnite in appearance, has metallic lead-gray color, red streak, H = 2, G = 4.81, and occurs in groups of slender prismatic crystals.

Mottramite ($(CuPb)_2V_2O_8 \cdot 2H_2O$). The vanadium of commerce was formerly obtained from this, blackish incrustations of mottramite upon the Keuper sandstone, Cheshire, England. Streak yellow, H = 3, G = 5.9.

Ochre, commercially, is a golden-yellow intimate mixture of clay with 20% or more of hydrated ferric oxide. Mineralogists use the name also for pulverulent yellow iron oxide (xanthosiderite) and for pulverulent red hematite.

Ozocerite, or mineral wax, is essentially a paraffine, colorless to white when pure, but usually greenish or brown, and possessing all the properties of beeswax except its stickiness. A little is mined in Utah and about 3,000 tons are imported annually from Galicia and Moravia. Used in crude state as insulation for electric wires. By distilling it the paraffine, used for candles, burning oils, paraffine, a product like vaseline and a heavy oil which, with india-rubber, constitutes the insulating material called okonite.

Patronite (vanadium sulphide). At the one locality of Cerro de Pasco, Peru, there is a vein 7 or 8 ft. thick of a nearly black material resembling slaty coal. About two-thirds of this is patronite and one-third metallic sulphides and free sulphur. Below this is 1 ft of coke-like material, chiefly carbon, which blends into a lustrous black asphaltite, 4 to 6 ft thick, containing more sulphur than carbon, but known as asphaltite. Specimens of these two associates are also rich in vanadium, and the roasted or burned ore is exported.

Petroleum is a mixture of hydrocarbons, obtained from the earth. It varies from a readily flowing liquid, to a thick viscous oil, and is usually of a dark brown or greenish color with a distinct fluorescence. Chemically the American petroleum consists largely of hydrocarbons of the paraffine series C_nH_{2n+2}, with smaller amounts of the series C_nH_{2n}, and C_nH_{2n-6}. The oils from Baku, on the Caspian, Rangoon, Galicia, and Java, contain more of the C_nH_{2n} or olefin series.

Roscoelite (vanadium mica). A mica of brown to brownish-green color, long known as an associate of gold in certain mines of California, and containing approximately 20% V_2O_3. It is now commercially obtained from a soft Colorado sandstone of greenish color, in which the roscoelite fills the interstices between the grains.

Thorianite ($ThO_2U_3O_8$). Small water-worn blackish cubic crystals found in the monazite gravels and used as a source of thoria. H = 5.5 to 6, G = 9.3. It is radioactive.

Thorite ($ThSiO_4$). Black or orange-yellow, zircon-like crystals and masses, occurring rarely in small quantity; used as a source of thoria. H = 4.5 to 5, G = 4.8 to 5.2. Decomposed or gelatinized with acids.

Umber is a drab-colored mixture of iron and alumnum silicates, containing manganese which becomes reddish brown on burning. Sienna is similar, but with less manganese and lighter in color.

Wad. Earthy to compact indefinite mixtures of oxides, especially of manganese, sometimes of copper, are known as wad. They have no constant characters, but may be determined as ores. Usually dark brown to black in color.

GEOLOGY

1. Introduction

A rock is a mineral or aggregate of minerals, forming an essential the earth; but many important mineral bodies, such as ores of metals, to be considered as rocks. Of about 1 000 species of minerals, only 2 are important as rock constituents.

The three great classes of rocks are: IGNEOUS, solidified from fusion; MENTARY, deposited in water or air; METAMORPHIC, recrystallized or otl altered igneous and sedimentary rocks, such that their original charac been obscured. Igneous rocks are believed to have been the predecesso source of all others (1, 2, 3).

An analysis, illustrating GROSS COMPOSITION of the outer 10 miles of the earth, in Sec I, Art 1. Compared with the percentages there stated, nickel and iron p become increasingly abundant toward the earth's center.

Most abundant elements of rock-forming minerals are: silicon, oxygen, alu iron, magnesium, calcium, sodium, potassium, and hydrogen; secondarily, chlorine, phosphorus, titanium, manganese, and sulphur. All other element the familiar copper, lead and zinc, and the precious metals, or an abundant atm gas, as nitrogen, are comparatively unimportant.

2. Chemical Composition of Rock-forming Minerals

Rock-forming minerals comprise silicates, oxides, carbonates, sul chlorides, phosphates, sulphides, and native elements.

Silicates are the most important, whence silicic acid, in various forms foremost acid in Nature. Three principal forms of silicic acid are repre in the rock-making minerals: H_2SiO_3 (metasilicic), H_4SiO_4 (orthosilicic $H_6Si_2O_8$. Pyroxenes, amphiboles, and leucite are salts of metasilicic Micas, olivine, anorthite, nephelite, garnet, and many minor miner orthosilicates. Orthoclase and albite are salts of $H_6Si_2O_8$. Some silicate only the usual bases, aluminum, iron, magnesium, calcium, and the al and are called ANHYDROUS; others, usually formed by weathering or alte of the first, contain hydrogen and oxygen in such proportions as to be off as water, and are called HYDRATED SILICATES. This distinction is re important by the general secondary character of hydrated silicates. Th anhydrous silicates in igneous rocks embrace the following mineral g feldspars and feldspathoids, pyroxenes, amphiboles, micas, and olivine. and less important are: zircon, titanite, tourmaline, and analcite. On we ing or other alteration, the hydrated silicates, kaolinite, chlorite, and serpe usually result. Metamorphic rocks contain a few characteristic silicate sides the common ones of igneous rocks, viz: staurolite, sillimanite, cy andalusite, scapolite, and epidote.

Oxides are next important, of which quartz (SiO_2) stands first, being dant in all the great classes of rocks. The related form of silica, chalce and the hydrated variety, opal, should also be noted. Next are the oxi iron, magnetite and hematite, and the hydrated form, limonite. With ma ite are associated chromite and ilmenite ($FeO \cdot TiO_2$). Water, whether or ice, is also technically a mineral.

Carbonates are calcite, dolomite, and siderite, with their intermediate tures. They are of chief importance in sedimentary and metamorphic occurring rarely in the igneous, except as products of weathering. The two SULPHATES, anhydrite and gypsum. One CHLORIDE, common salt,

...xtention. There is one PHOSPHATE, apatite, which, strictly speaking, is ...sphate and chloride or fluoride. Two SULPHIDES, pyrite and pyrrho... widely distributed. The one NATIVE rock-forming element is graphite.

3. Rock-forming Minerals (1, 2, 3)

Minerals of the igneous rocks are grouped according to their usual order ...stallization into: 1. Iron ores and minute associates. 2. Ferromag... silicates (olivine, pyroxenes, amphiboles, and micas). 3. Feldspars ...eldspathoids (plagioclase, orthoclase, nephelite, leucite, and analcite). ...artz, in acidic and higher medium rocks only. For descriptions, see ... Tables I–VIII.

Minerals of the sedimentary rocks are principally fragments of minerals ... igneous rocks. Quartz is most resistant to solution, alteration, and abra... and therefore appears in almost all sands and sandstones. The others ... frequent. After quartz, carbonates are of chief interest. Calcite and ... constitute the limestones, sometimes with slight admixture of siderite. ...ite, from feldspars, enters the fine sediments. The two sulphates, ... the more abundant, and anhydrite, appear only in sedimentary rocks. ...me is true of the chloride, rock salt.

Minerals of the metamorphic rocks. The components of both sedimentary ...eous rocks, when deeply buried, with attendant heat and pressure, re... at times to distinctively metamorphic minerals. Silica, being om... survives as quartz. The aluminous components afford andalusite, ...ite, and cyanite. Magnesian, iron, and aluminous compounds yield ...ast biotite and occasional epidote. Lime, in association with ferric iron ... alumina, makes garnet possible, but orthoclase may become muscovite. The ...es are important components. The ferromagnesian minerals (chlorite ... serpentine) are derived from magnesium- and iron-bearing originals.

Summary of Rock-forming Minerals

Igneous Rocks. QUARTZ
FELDSPARS: orthoclase, plagioclase
FELDSPATHOIDS: nephelite, leucite, analcite, melilite
PYROXENES: hypersthene, diopside, augite, soda-pyroxenes
AMPHIBOLES: hornblende, soda-amphiboles
MICAS: biotite, muscovite
OTHER MINERALS: olivine, magnetite, ilmenite, apatite, zircon

Sedimentary Rocks. Fragments from igneous rocks, especially quartz and feld...spars; kaolinite, calcite, dolomite, siderite, limonite

Metamorphic Rocks. Quartz, feldspars, biotite, muscovite, hornblende, epidote, ...garnet, sillimanite, andalusite, calcite, dolomite, serpentine, talc, chlorite

4. Igneous Rocks

Structures and textures. In a broad way, igneous rocks, as contrasted ... sedimentary and metamorphic, have a massive structure; that is, their ...s are not arranged in parallel or distinct layers. Massive is some... used as a synonym of igneous. Examined more in detail, as in hand-...s, they have 4 common textures. Where the molten mass has been ...dly chilled to crystallize, the texture is GLASSY. This texture appears ... borders of thin masses, on upper surfaces of lava flows, and, in rela...tively basible varieties, it may extend through an entire flow. It is most ...nt in siliceous rocks, which have high fusing points; it is rare in the ...ic and scarcely known in the basic. Where molten masses have cooled ...ewhat rapidly, and yet not so quickly as to prevent crystallization, very fine-

grained textures result, called FELSITIC. But, if older, larger, and **alrea** formed crystals at the time be swimming in the magma, which then **cry** in relatively small components, the texture is called PORPHYRITIC. **T** crystals are called PHENOCRYSTS and the matrix the GROUND-MASS. crysts of acidic rocks are chiefly quartz and feldspars; the dark ferroma silicates are much less common. In medium rocks, quartz practically **fa** feldspars are associated with more of the ferromagnesian minerals. **I** porphyritic rocks, feldspars decline, while augite and olivine, and **very** biotite and hornblende, gradually replace them. When a molten **magm** tallizes into an aggregate of fairly coarse components of about the **same s** texture is GRANITOID (like granite). Rarely, in these coarsely **crystallin** the feldspars become unusually large and stand out in contrast **with the**

As a result of explosive outbreaks at volcanic vents, igneous rocks are **sometime** out as fragments of all sizes, from impalpable dust to large bombs. **The fra** settle down on the sides of the cone or at greater distances, and yield rocks **with** fragmental texture, allied to sediments. If coarse they are called BRECCIAS; **if fine**

Chemical composition of igneous rocks. SILICA ranges from **abou** to a theoretical minimum of 0% in certain igneous iron ores; **only i** cases does it fall below 40%. Igneous rocks containing above 65% **sili** called ACIDIC; those with 55 to 65%, MEDIUM; below 50%, BASIC. Of **AL** the superior limit is 25 to 30%; general range, 12 to 18%; minimum, **ne** IRON OXIDES are low, 1% or less, in the most acidic rocks, but **increase** basic to 10 to 20%; in rare extremes, 90 to 95%. MAGNESIA **sinks to a** trace in the acidic, rising with fall of silica to 30% in the extremely **basic.** is low in the acidic, gradually increasing to about 15% maximum **in c** basic rocks. POTASH is highest in the rare leucite rocks, reaching 10 or it ranges from 4 to 7% in medium rocks with much orthoclase, and **disap** in basic types. SODA has a similar maximum in the rare nephelite **rocks** the same range in medium rocks rich in albite, approaching extinction **i** extremely basic. WATER, of 0.5 or 1%, usually indicates weathered **rocks**

It is important to connect chemical compositions with the **resultant mineral** vice versa. Chemical composition obviously determines the minerals, and, in so extremely acidic rocks have relatively high fusing points and chill more **easily, it al** fluences texture.

Classification of igneous rocks shown in Table 1 has general **accept** by geologists. Rocks range from acidic on left of table to basic on **right;** quickly-chilled rocks above to slowly-cooled rocks below, a still **lower lin** fragmentals marking transition to sediments. The forms assumed in **Na** are in extreme left-hand column; to be defined after the **descriptions.** rocks are further subdivided in vertical columns on basis of **mineralogy.** I spars and feldspathoids are the fundamental basis of subdivision; **other mi** als are subordinate.

The table gives a general view of the igneous rocks and defines those commonly in mining. For close determination greater refinement may be **desirable.** In s mining districts in the western U S are found the GRANO-DIORITES (intermediate betw granites and quartz-diorites), not mentioned in table. They have about the **same amo** of orthoclase and plagioclase. Intermediate between syenites and diorites are the M ZONITES. If they have a little quartz, but not as much as grano-diorites, they are ter quartz-monzonites. Butte granite, containing the copper veins, is usually describe quartz-monzonite. Several great bodies of "porphyry coppers" are in monzon porphyries. The varieties of gabbro containing hypersthene instead of common au are called NORITE; important because they contain the nickel-copper ores at Sudbu Ont. (For meaning of names of other rare igneous rocks, sometimes appearing in porta, see glossary in later editions of Kemp's "Handbook of Rocks.")

Crust Surface Flows	Glass	Acid Glasses, Obsidian, Pearlite, Pumice, Pitchstone			Andesite-Obsidian		Basic Glasses, Scoriae, Tachylyte, Basalt-Obsidian						Ultra-basic rocks

Glassy rocks are the most evident results of cooling from fusion. T almost always acidic and are represented by the rhyolites and daci scribed later. More basic varieties are known, but are less frequent. monest glasses are the OBSIDIANS, black, red, and brown, with 0.5 to 1% They may be assumed to be quickly-chilled rhyolites or dacites. PUMIC excessively cellular obsidian. A rarer glass, which chills into an aggre shot-like spheroids, is PEARLITE or PEARL-STONE, usually containing 2 water. The last glass deserving mention is the rare, resinous variety PITCHSTONE, having 5 to 10% water and is more easily fusible with bl than the others.

Rhyolite-granite series embraces igneous magmas containing: silici 80%; alumina, 12 to 15%; iron oxides, 1 to 3%; magnesia, less tha lime, 1 to 2%; potash and soda, 5 to 8%. They are common in Natu on crystallizing yield finely to coarsely crystalline rocks, consisting ch orthoclase, acidic plagioclase, and quartz, together with relatively small a of the dark silicates, biotite, hornblende, and augite, stated in order quency. Light-colored minerals are in great excess.

Rocks of this series are: RHYOLITE (syn, liparite), felsitic or partly glassy text phenocrysts; RHYOLITE-PORPHYRY (syn, quarts-porphyry), felsitic ground-mass dant phenocrysts; GRANITE-PORPHYRY, predominant phenocrysts, subordinate mass; GRANITE, granitoid texture, components of about the same size, but f sometimes abnormally large. PEGMATITES: crystallization of granite is often panied by separation of portions of the magma, in association with abnormall admixtures of dissolved gases. These portions pass outward into wall-rocks a often for great distances and in large size; on crystallizing, they yield very co gregates of same minerals as appear in granite itself, with many rare elements trated in them, and are called pegmatite.

In this series the prominent minerals are feldspars and quartz; dark silicates a ordinate. They are closely related to the dacite-quarts-diorite series, from which tinguish them microscopic examination may be necessary. The distinction is pra of small moment. This series is very abundant and widely distributed. Its tu breccias are also frequent.

Trachyte-syenite series embraces igneous magmas containing: silica, [illegible]; alumina, 15 to 20%; iron oxides, 1 to 5%; magnesia, 1 to 2%; lim [illegible]; potash and soda, 7 to 12%. They are much less common than the rh granite series. On crystallizing they yield finely to coarsely crystalline rock consisting of orthoclase, acidic plagioclase, and usually notable proportions dark silicates, biotite, hornblende, and augite, one or several. Quartz fai at most, is extremely subordinate. Light-colored minerals are in excess.

Rocks of this series are: TRACHYTE, felsitic texture, few phenocrysts; TRAC [illegible] phenocrysts; SYENITE, granitoid texture, components [illegible] ground-mass; SY [illegible] sometimes abnormally large feldspars. Syenitic-pegm [illegible]

In this series [illegible] dark silicates, subordinate. Li [illegible] granites. Tuffs and breccias are k

Phonolite-nepheline-syenite series embraces igneous magmas contai [illegible] magnesia, 1 to [illegible]. They occur infrequently. [illegible] consisting of o [illegible] sodalite, and pyro [illegible]

Rocks of this series are [illegible] with few phenoc [illegible] phenocrysts, of which orth

...dalite being usually confined to ground-mass; NEPHELITE-SYENITE-PORPHYRY, ... phenocrysts, subordinate ground-mass; NEPHELITE-SYENITE, granitoid ... rather fine to extremely coarse varieties, shading into pegmatites.

... these rocks, orthoclase is most prominent, but in the last-named, nephelite ... abundant. Many varieties have been recognized, depending on entrance of ... less usual than those named, and the decline of normal components. Sodalite ... very prominent. Biotite and hornblende are not so frequent as pyroxene. ... with leucite are known, but are far less common than those with nephelite.

...ite-quartz-diorite series embraces igneous magmas containing: silica, ... alumina, 12 to 15%; iron oxides, 1 to 3%; magnesia, 1 to 3%; ... to 4%; soda and potash (soda in excess), 4 to 7%. They are common ... centers. On crystallizing they yield finely to coarsely crystalline ... consisting of plagioclase, less orthoclase, and quartz, as the most promi... minerals, with biotite, hornblende, and pyroxene, one or several. The ... colored minerals are in excess.

... of this series are: DACITE, felsitic or partly glassy textures, few phenocrysts; ... PORPHYRY, felsitic ground-mass, with abundant phenocrysts; QUARTZ-DIORITE ... ..., predominant phenocrysts, subordinate ground-mass; QUARTZ-DIORITE, granit... ...

...desite-diorite series embraces igneous magmas containing: silica, ... to 60%; alumina, 15 to 18%; iron oxides, 4 to 9%; magnesia, 2 to 7%; ... to 8%; soda, 3 to 5%; potash, 2 to 3%. They are very widespread. ...stallizing, they yield finely to coarsely crystalline rocks, consisting of ... ...clase, a little orthoclase, and biotite, hornblende, or augite, one or several. ...-colored minerals are in excess and are the chief phenocrysts. The ... have usually light gray colors.

... of this series are: ANDESITE (varieties, mica-andesite, hornblende-andesite, ...-andesite), felsitic textures, few phenocrysts; ANDESITE-PORPHYRY, felsitic ground... with abundant phenocrysts; DIORITE-PORPHYRY, predominant phenocrysts, ground... subordinate; DIORITE, granitoid texture. Andesites are important in many western ... districts; in the recently extinct and active volcanoes along Pacific coast, in ..., and in other parts of world.

Basalt-gabbro series embraces igneous magmas containing: silica, 40 to ... alumina, 16 to 20%; iron oxides, 6 to 15%; magnesia, 5 to 10%; lime, ... to 12%; soda, 2 to 4%; potash, 1 to 2%. They are very widespread. On ... stallizing they yield finely to coarsely crystalline heavy rocks, consisting of ...oclase, little or no orthoclase, and large proportions of pyroxene, olivine, ... magnetite. The dark silicates are in excess and give rocks dark gray or ... colors.

Rocks of this series are: BASALT, felsitic textures, few phenocrysts; BASALT-PORPHYRY, ... ground-mass, abundant phenocrysts; GABBRO-PORPHYRY, predominant pheno... subordinate ground-mass; DIABASE, granitoid texture, feldspars long rectangular, ... irregular and occupying spaces among the well-crystallized feldspars; GABBRO, ... components as broad as long.

...-gabbro rocks are very abundant. Phenocrysts are almost entirely olivine and ... The peculiar texture of diabase, due to feldspars completing their crystalliza... before the pyroxenes, contrary to rule, gives them a special place. Varieties of ... afford special varieties of both basalts and gabbros. Hornblende and biotite ... observed; nephelite, leucite, analcite, and melilite sometimes appear and may ... the plagioclase. All feldspars and feldspathoids may fail, giving the rare ba... ...ingite and augitite, and the rare gabbros, peridotite and pyroxenite (Table 1).

Ultra-basic rocks. There are a few rare igneous rocks with less than 40% silica and ... high bases. The most important are the igneous magnetites, often ... ; in some places they are independent dikes and sheets, in others, segre... ... in igneous rocks.

7. Forms Assumed by Igneous Rocks

... field, igneous rocks are found in dikes, necks, bosses, stocks, surface ...sive sheets or sills, laccoliths, and batholiths. The size and shape ... bodies exercises an important influence on texture of the component ... small bodies chill quickly and are glassy or felsitic; large bodies cool ... and are porphyritic or granitoid. Designating one horizontal dimen... length (*L*), the horizontal dimension at right angles to *L* as breadth (*B*), ... vertical dimension as depth (*D*), a mathematical expression can be ... formulated for each type.

...ikes are long, narrow bodies of igneous rock, filling fissures in older rocks, ... it has entered in molten condition. In dikes *L* and *D* are great, *B* ... small; they vary from less than 1 in wide and a few yards long, to ... of a mile in width and many miles in length. They usually have steep ... often intimately associated with ore-bodies, and in one place or an... embrace all varieties of igneous rocks. They may mark the last out... of a series of eruptions in a particular district, and are then usually very ... at Cripple Creek, Colo.

...ikes may radiate from an igneous center for miles into the surrounding strata, as in ... Mts, Mont, or the Trinidad coal region, Colo. They may appear hundreds of ... other known igneous rocks, as in the coal measures of S W Pennsylvania. A ... from solidified molten rock, even though a magma be regarded as a solu... fully all of which crystallizes *in situ*, is contrasted with a vein, similar in shape ... to the walls, but which is deposited from solution, the solvent passing ... in the case of pegmatites, it is not clear whether the term dike or vein should ... they may be considered the result of aqueo-igneous processes of fusion.

...eck is the solidified mass of lava that remains in the throat of a volcano ... last outbreak. When first congealed, it connects the lava that has ... from the crater with the unerupted residue in depth, just as a human ... ects head and trunk. As seen in the field, it is usually a decapitated ... that it is exposed to view only after removal of the lava flow and much ... by erosion. *L* and *B* are small, *D* great.

...anoes, which yield both lavas and explosive products, the neck may be part ... and part breccia. Necks project in a rudely columnar manner from remnants ... crater and from débris furnished by their own disintegration.

...sses are roughly cylindrical masses of igneous rock, projecting above sur... wall rocks like the boss on an old-time circular shield. Coarse granite ... rite, because of its relative resistance to erosion, often projects from ... mica-schists or other softer rocks. Bosses differ from necks in ... due to volcanic activity. As in case of necks, however, *L* and *B* are ... small, *D* great.

...cks are large, roughly cylindrical masses of intrusive porphyritic or ... rock, in the midst of older walls. They do not necessarily stand in

relief, but otherwise are much the same as bosses; *L* and *B* are small w spect to *D*, although absolutely of rather large size.

The name "stock" is the German word for floor or story in a house, and was to masses of igneous rock of cylindrical shape, because certain granite bodies of r outline, containing disseminated cassiterite, were formerly mined in horizontal s floors. Finally the mass of rock itself came to be called a stock. For good i tions, see Telluride folio of U S Geol Surv.

Surface flows are produced when lava wells out from a vent, and flow surface in a relatively thin sheet; *L* and *B* are large, *D* small. In upp under portions are many cavities, caused by expanding gases; the middl is usually dense, and in a thick flow may be comparatively coarse-gr The cavities are flattened and rounded like an almond, whence, from the they are called AMYGDALOIDS.

The top of a flow may be a rough, slaggy scoria, even consisting of cakes of and broken crust. Where dissolved gases have all escaped before consolidatic while lava is yet molten, the final chilled surface may be comparatively smooth. flows may bury one another in succession, or be covered with later sediments. are distinguished from intrusive sheets, because their heat can at most affec underlying rocks, not those formed above them after cooling; whereas intrusive bake both walls. More than 100 successive surface flows of basalt have been cut h shafts in the Lake Superior copper district.

Intrusive sheets or sills are masses of igneous rock which have been between strata of older rocks, and have solidified parallel with them. *L* are great, *D* small. The shape resembles that of a surface flow, and w surface flow resting on sediments is buried under subsequent beds the re much the same. The heat of intrusive sheets, however, always affects the ments above and below them, and sometimes produces important contact

Intrusive sheets vary from a few feet thick, and of no great known extent, to sill as the Palisades of Hudson River, visible 50 miles, traceable by drill 25 miles its thickness reaches 600 ft, but is usually less. Intrusive sheets doubtless rise fro depths along fissures, like dikes, but then turn sidewise between strata along a least resistance. They are sometimes associated with ore-deposits, as at Lea Colo, and Mercur, Utah.

Laccoliths are a variation of the intrusive sheet and are lenticular in shape. sill be supposed to start from its feeding dike, sidewise between strata, and to easier to raise the overlying beds of a limited area than to force its way with u thickness far and wide, a lenticular mass will result, tapering from a central max thickness to a thin edge. Hence, *L* and *B* are relatively large, *D* smaller but va Laccoliths which are fed outwardly from a central supply fissure are symmetrical this fissure is sometimes a fault, with hard strata opposite soft ones, so that the sive can penetrate outwardly only on one side. Unsymmetrical masses, practically laccoliths, result. Laccoliths heave up overlying strata in domes, and when the eroded the laccolith is exposed in midst of outwardly dipping beds. The entra laccoliths may have been aided by incipient folding or arching of beds under co sion. Laccoliths are widespread in the western states. The name was coined by Gilbert from the Greek word for cistern, as the shape suggested the ancient dome-co vaults for storing water.

Chonoliths are irregular intrusive bodies, either filling a pre-existing cavity, or ing apart the rocks to make a way for itself. The name was coined by R. A. Daly the Greek word for a mould in which metal is cast. No definite expression in ter *L*, *B*, and *D* is possible.

Batholiths are huge masses of intrusive rock, of irregular shape and great ex *L*, *B*, and *D* are all great. Granite masses, square miles in area and sometimes miles in volume, are illustrations. They are specially abundant in pre-Cam strata.

1. Forms Assumed by Sedimentary and Metamorphic Rocks

distinguishing feature of sedimentary rocks is their arrangement in parallel during formation. Variations in deposition of sediment from high and storms and calms, floods and droughts, produce contrasts in coarseness ness. At the outset they are flat, except for the slight inclination of the en, and irregularities due to delta formation and swift currents. The in- sition often seen in exposures today is due to subsequent disturbances.

Stratification. The smallest division of a sedimentary rock is a LAYER or It may be a fraction of an inch thick and marks one period of es- abundant deposit. Layers go together to form BEDS, the natural sedimentary rocks. Bedding planes are recognizable and thick- and ed sedimentaries are distinguished. Beds combine to constitute a or tabular mass of one kind of sedimentary rock between others are different. A stratum may range from 1 to 1 000 ft thick. Thin are usually called SEAMS, as in case of coal. Limestones, shales, and s afford thick strata. In geological mapping, a thick and persistent is often called a FORMATION.

sedimentary rocks present all the features of the bottom, or of the strand between low water: as ripple marks, tracks, stranded shells, rill-marks, mud-cracks, ange from swift currents, irregular beddings, and cross-bedding in individual deltas. Since the greatest thickness of sediments gathers along subsiding with attendant advances of sea over land, there are found in normal suc- conglomerates which represent old shore shingle, followed by sandstones, repre- shore shallows; next shales, corresponding to deeper, quieter water; lastly, ating still deeper water, free of mechanical sediments, are limestones, con- ny of organic remains. This normal succession is not always found, since ren, etc. destroy uniformity, but it is not infrequent. There are also desert ons, wherein wind-blown particles are important, and are associated with temporary streams, lakes, and floods. Land accumulations are character- ed from oxidation of iron.

2. Rock Disturbances

wide observation has shown that the rocky outer portion of the earth subject to many disturbances. Great masses may rise or sink without the local attitude of the rocks. These continental movements are of interest, but seldom of importance to the engineer. Localized move- to elevation of a long and relatively narrow belt in a mountain chain, rbances incident to intrusive entrance of bodies of igneous rock, are portant. The results of these movements are termed FOLDS and FAULTS.

lds are bendings in strata, whereby each layer assumes a curved form, ing a portion of a cylinder. When classified in order from least to lds embrace MONOCLINES, ANTICLINES, INES of several types, DOMES and BASINS.

Monoclines (Fig 1) are terrace-like bendings of with inclination varying in amount, but same direction, as the name implies. A p of the terrace marks a belt of especial the strata affected, and may be accom- numerous cracks. At foot of the terrace d roll in reversed direction, with attendant nd cracks. In the upper roll, overlying beds are subject to tension. g to compression; in the lower roll, the upper beds are compressed, tense. Between these areas is necessarily a surface of no strain.

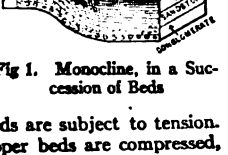

Fig 1. Monocline, in a Succession of Beds

Monoclines which involve porous beds, such as open-textured sandstones tight shales, are sometimes important places for accumulation and storage o gas and petroleum. The search for these is essentially an endeavor to locate, drill, favorable monoclines or gentle anticlines. Monoclines have been desc arrested anticlines. In a series of sediments comprising shales or other so monoclines or even more violent folds in stiffer strata may at depth disappea in the adjustment of soft overlying shales, the plastic movement of which take distributes the fold until it is diffused and lost. The name monocline (or m structure) is sometimes applied to a remaining half of an eroded anticline or the other half of which is not apparent; inclination of the beds is all in one dir

Anticline and syncline (Fig 2) are complementary terms; one ra pears without the other. An anticline is an arch-like bend, a synclin responding trough. The upper pa anticline is called the CREST; its sides, LIMBS or LEGS; the central running parallel with the axis of t centric partial cylinders, the surf which are represented by each fold is the AXIS. The bottom of a syn the trough. Beneath anticlinal cr synclinal trough the beds are es strained and cracked; the cracks to gape upward in the anticline and ward in the syncline. The limbs of each type of fold are less straine crest or trough. Thus, good building stone will be found on the limbs than at crest or in trough. On the contrary, veins and mineral deposi circulating waters find natural resting places in crest and trough.

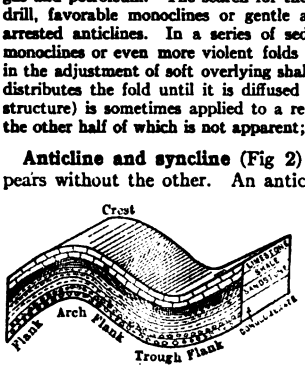

Fig 2. Anticline and Syncline, with Horizontal Axis

Anticlines and synclines, when followed for a mile or more, seldom have ho axes as shown in Fig 2. The axes usually pitch downward (Fig 3), though th afterward rise again. In Fig 2, the component beds, if eroded, would appear at surface in parallel bands. When pitching folds are eroded, the several beds appear at surface as concentric curves (Fig 3). In anticlines the upper or later beds are outside, the under or older, inside; in synclines the under or older beds are outside, the upper or later, inside. Because of these relations, geologic structure may sometimes be inferred from a colored geologic map.

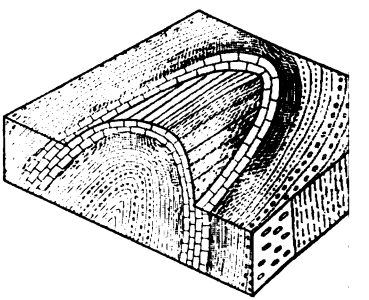

Fig 3. Pitching Anticline, Showing Concent Curving Outcrops of Eroded Beds

Anticlines received their name because the observer was assumed to stand at the crest, from which the beds inclined outwardly in opposite directions; hence the prefix "anti," for "opposed." Standing in the trough of the syncline the observer se inclined beds sloping toward him, hence the prefix "syn," for "together." Ant and synclines of which the inclination is the same on both sides of axis (see dia are called SYMMETRICAL. Symmetrical folds may vary from those of compara slight disturbance to tightly compressed folds. In the former, where the limbs of are separated by other beds, the fold is called OPEN; but where from extreme co sion the limbs of a single bed are brought tightly together, the fold is CLOSED. shows open symmetrical folds; Fig 4 closed symmetrical folds. A limiting case anticline, speaking mathematically, is the DOME, in which the beds pitch radially directions from a central point. The variable direction of the inclination has sug

...ne QUAQUAVERSAL. A dome is an anticline of which the axis is reduced to a point. ... are chiefly developed above laccoliths; seldom in other relations. A BASIN is a ... the axis of which is a point, toward which the strata converge.

... this strict sense are rare, and result from local removal of ... and collapse of strata. The term is also used in the geology ... of a synclinal arrangement of strata, wherein a rising pitch ... in opposite directions brings the measures to the surface. ... thus form concentric canoe-shaped or spoon-bowl syn-...

From relatively slight differences, ...ture may increase until the overturned portion rests on an underlying ... Such folds may even be S-shaped (SIGMOID) or RECUMBENT. On a ... scale, these often occur in metamorphic districts; on a large scale they ... mainly in regions of violent disturbance.

... names may be used, such as the Jura type for symmetrical folds; Appalachian ... ...e those steeper on one side than the other (Fig 5). Closed folds are those of which the limbs are squeezed so tightly at one spot as to cause a great bulge of an upper or under core of rock. When the surrounding strata incline away radially from the compressed area, like ribs of a fan, the fold is called a fan-fold.

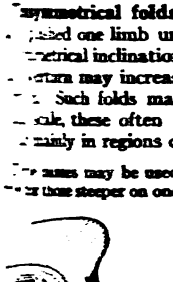

Fig 5. Overturned Fold ... Appalachian Type

Folds vary in size from small wrinkles and puckers, as in schists, to arcs having chords of yards, miles, or hundreds of miles. Folds are sometimes designated as of the first, second, third, or higher orders. A mountain range, consisting of an anticline or a syncline, is respectively called an ANTICLINORIUM or SYNCLINORIUM, the Greek word for mountain being added to type of fold. When great flat folds occupy an appreciable part of earth's surface, they are called respectively GEANTICLINES and GEOSYNCLINES, prefixing Greek word ...th to name of fold. Folds are of great importance in engineering work, not only in ... bedded minerals like coal, salt, and some iron ores, or in the discovery of petro- ... and gas, but also in connection with railway tunnels, aqueducts, and other engi- ...ing work.

Dip and strike. DIP is the angle of inclination of a vein or bed below hori- ... STRIKE (course or bearing) is the direction of line of intersection of an ... vein or bed with a horizontal plane.

... dip angle is the angle between two perpendiculars, one in the inclined plane, the ... the horizontal, let fall from a common point on their line of intersection (the ... The strike is stated in degrees and minutes, E or W of N or S, for example ... E. Since plane of dip is at right angles to line of strike, it is recorded in de- ... E or W of strike; thus, a strike of N 25° E and dip of 50° N W signifies that the ... in which dip is measured runs 65° west of north. Some observers note exact ... and amount of dip, leaving strike to be inferred. Thus, a record of a sand- ... dipping 50° in a direction N 65° W, implies a strike of N 25° E. Fault-breccia. Movement of fault
or of one wall on the other, often cr
adjacent rock to a mass of angular
ments, mixed with more finely commi
material. Circulating waters may ce
the whole into a solid mass, by depo
new minerals, sometimes producing val
ore. This mass is a FAULT-BRECCIA. Fragments of any bed, dike, or
involved in the fault movement, will be dragged along from stationary si
direction of movement; or will be left behind by moving side; and if foll
along fault plane, will indicate direction of movement. Such fragments fu
valuable evidence and by F. T. Freeland have been aptly termed the TRA
THE FAULT. Should a vein be cut off by a fault, with attendant breccia,
ments of the vein should be sought in the breccia and the trail followe
pick up continuation of vein.

Drag. Faults often cut relatively soft beds, as shales or shaly sandsto
Friction of the walls upon each other causes a downward bend in the bec
stationary or lifted side and an upward bend in those of the moving or drop
side. These bends, called DRAG, show the direction of movement (Fig
Drag is not found in strong rocks, like granites or heavily-bedded limesto

Slickensides are polished and usually grooved surfaces, often caused
movement of walls of a fault or vein. Upon the wall-rock the grooves indi
direction of movement, but do not necessarily show which side has gone up
down, or laterally.

Some observers have thought that by scraping finger nail or finger across the groo
one side of them will be found steeper than the other. If the grooves are tested in sl
ensides on underside of plane of movement, such steep ridge is considered to be

side of groove, or the side which resisted bearing down of hanging wall while moving normally downward in fault plane. It will thus indicate the actual direction of movement. Should the steep ridge be on upper side of grooves, an upward movement of hanging wall is indicated. Others have thought that when the finger is moved along a groove the greater roughness is felt in the direction of movement of the part felt. Striæ on fragments in fault-breccia are of little significance, since they are not in place.

Horses are large disconnected masses of wall rock, involved in faults, or produced by forking of a fault fissure around a split-off fragment, and especially closely related to subsequent vein-formation along fault.

Shear-zones. When a fault movement is distributed along a number of closely spaced planes not widely spaced, the wall rocks are broken into parallel tabular masses, and are said to be SHEETED. The resulting fault is "distributed," and the sheeted strip is a SHEAR-ZONE. GOUGE is a sheet of clay, often occurring along the outer edge of fault breccias, especially those subsequently mineralized by circulating waters. Other names are: SELVAGE and FLUCAN.

Fault-scarp. If a fault involves an appreciable vertical component, the relatively lifted side may stand out as a terrace or escarpment, the fault-scarp. This soon wears it down, so that fresh fault-scarps are rarely recognizable. They have sometimes aided the deposition of ore bodies by furnishing waterfalls. When they are developed across an older mineral deposit, serious displacement may be caused.

Rules for solving faults have been formulated by Schmidt (11), Zimmermann (13), Freeland (7) and others. In studying a fault, observe trail, drag and slickensides. Stratigraphical succession, if known, will reveal amount of displacement. Bore-holes are useful. Models assist, and are sometimes equivalent to projections on paper. If there be no evidence to contrary, the assumption that fault is normal is justified, because most faults are such. Nevertheless, experience shows that a reverse fault occasionally appears in a series of normal faults, that shift faults may occur, and that fault movement may be oblique (normal at one extreme of fault plane, reverse at other). On entering a fault, a mathematical solution is attractive, but, despite many text-book discussions, the necessary data are seldom obtainable. Attention should be concentrated on the fault plane and the movement along it (12). The dislocated portion of a tabular body is to be sought, presenting a broad face if rightly attacked. As a rule, it is easier to drift horizontally, than to sink or raise; the procedure is largely determined by the way the vein or bed lies. Where a series of stratified rocks, the succession and thickness of which are known by previous mining operations, by study of the surface, or by borings. Beds on far side of fault is recognizable, and its place in the series known, direction and amount of movement may be determined. As gulches often follow faults, because of easy erosion of crushed rock, faults may sometimes be found more readily by study of surface exposures than by observation underground. Directions of slickensides, drag, and trail, commonly in faulted stratified rocks, are highly significant. If none of these evidences decisive in dealing with a mineral deposit cut by a fault, there is strong probability that the fault is normal. On this assumption, if a fault be encountered on its under side the rule is to cross it and sink; if on its upper side, to cross it and raise. This is expressed in the old rule: "follow the obtuse angle." But, if the fault happen to be reverse, the rule would lead in wrong direction.

In dealing with steeply dipping veins in massive rocks, or steeply dipping beds of stratified rocks containing coal seams or other interstratified deposits, the suc-

cession of strata must be known to determine the movement. Then, s tentatively as a normal fault, due weight must be given to throw and sh possible components of diagonal movement. That is, besides the heav throw of a normal fault, a large shift-component might cause displac

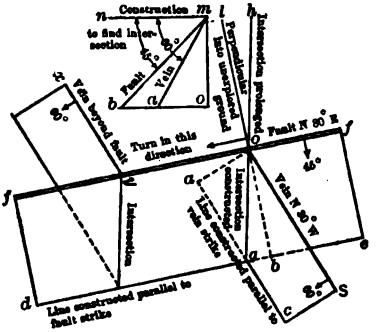

Fig 9. Zimmermann's Solution of a Fault (Projection on Horizontal Plane)

opposite to that anticipated, i of straight down the dip. I case, the occurrence of slicker trail, and drag may be essen correct solution.

Zimmermann's rule (13), fo faults, cutting steeply dipping Suppose (Fig 9), in driving a l vein *so* striking N 30° W and d 60° W, a fault *ff* is met, strik 80° E and dipping 45° S. At in tion *o*, draw *ob* perpendicular to of fault, and prolong it toward *l*, the fault. Project upon plane the intersection *og* of fault an Line *og* is horizontal, and passes ob through *o*, into unexplored grou ward *h*, on one side or other Then, if exploratory drift on f of fault be turned from *oh* tow and parallel to strike of fault, the displaced segment *xy* of vein will in most ca found.

The horizontal projection *og* is found as in small diagram of Fig 9. Draw hor line *mn*, lay off *ma* and *mb* to represent dips of vein and fault; draw *mo* perpen and *ob* parallel to *mn*. Then *oa* and *ob* are the distances by which, in descending a cal distance *mo*, the planes of vein and fault depart horizontally from vertical. I part of Fig 9, *oa* and *ob* are drawn respectively perpendicular to strikes of vein and fau *ac* and *de*, passing through *g*, are parallel to those strikes. Whence *g* lies in the horizontal projection of intersection of vein and fault.

In Fig 10 is shown a similar relation of vein and fault, except that the vein lies east and exploratory drift should turn east, as shown. Both solutions depend on assumption that the hanging wall of fault (*i e*, its south wall) has slipped with little shift down on its footwall. With a strongly diagonal movement the fault might still be normal, but the solution might lead miner in wrong direction. Therefore check all rules by trail, drag, slickensides, etc.

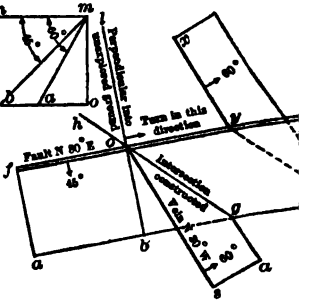

Fig 10. Zimmermann's Solution of a Construction as in Fig 9, but Vein I Whence Exploratory Drift Turns *E*

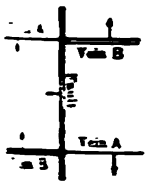
The following additional terms apply to faults. In tilted, stratified rocks, faults striking parallel with the strata are STRIKE-FAULTS, often resulting when folds pass into faults. Faults running across strike and parallel wit of dip are DIP-FAULTS. STEP-FAULTS are series of parallel faults, dipp same direction. The HADE is the angle made by a fault plane with a v plane; hence, hade is complement of dip, and is a superfluous term.

Various puzzling cases of faulting have become classic. Fig 11 shows a Cornis from de la Beche; Fig 12, a case of two contrasted pegmatites in Sweden, obser A. G. Högbom. Two parallel veins may be so faulted as to bring dislocated part opposite sundered end of another, and temporarily conceal the existence of a fau

... shift fault, cutting a vein at right angles to vein's strike, the amount of shift ...ved to grow gradually less in depth, leading to inference of a HINGE-FAULT, or ... ROTATIONAL FAULT.

...mal faults are often explained as due to tension strains in earth's crust, leading ... apart of the two sides of fault, and the slipping down of upper portion on ...face. they have been called tension or gravity faults.

...ults, by contrast, are called compression or THRUST ... they often begin as overturned folds. If these stresses do produce their respective faults, then reverse faults should customarily have low dips, since, on approaching the perpendicular, friction would increase prohibitively. But, if tensional stress were relieved by a series of parallel faults, and one fault block were to drop below its neighbors, there would be a normal fault on one side of dropped block and a reverse fault on other.



... 12 Two Veins, ...verging Dips, ... Below their In... by a Normal

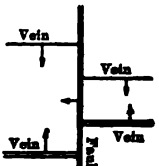


Fig 11. Two Veins, with Converging Dips, Normally Faulted

Compressive strains along the strike can easily develop normal faults by downward bulge of hanging wall and upward bulge of foot. Where comparatively short faults die out at each end, this explanation has weight. Again, assuming that in depth rocks are capable of viscous flow and transfer, pressure transmitted upward from such moving masses ... faults from stresses wholly different from any previously mentioned. Where ... inclined, fault blocks with the larger base would be relatively lifted, as com... those having smaller base. Foot-walls would therefore rise relatively, caus... normal faults (4, 5, 6, 8).

12. Joints, Unconformities, Outcrops, Erosion

Joints are cracks which cross strata and masses, without producing dislocation. Notwithstanding absence of dislocation, there may be difficulty ...inguishing between joints and distributed faults of slight displacement, ... produce sheeted structure.

... are due to easing of some kind of strain; as contractions in cooling of igne... expansion of cold rock under the sun's heat, shrinkage from drying of water-... sediments, tensional strains at crests of anticlines or in outer layers in bottoms ... and torsional stresses produced over wide areas by warping of earth's crust. ... rocks break into polygonal columns of greater or less regularity. In joints ... by contraction of igneous magmas during consolidation, the long axes of the ... are theoretically perpendicular to cooling surface. If the magma be homogeneous ... of heat uniform, regular hexagonal columns result, parted also across their ... cup-shaped joints. Occasionally, as at Giant's Causeway, theoretical perfection ... attained; usually, the columns are of all numbers of sides, from 3 to 8. Similar ... from drying.

... heat of sun and weathering cause massive rocks to shell off in thin layers. ... blocks produced by jointing may become rounded boulders. In granite quarries ... in great concentric curves, like a huge onion, has probably been caused ... contraction strains in cooling, or compression strains in earth's crust. Cracks ... upward at crests of anticlines, and gape downward in troughs of synclines, ... features of folds. In certain districts of flat sedimentary rocks (as in south... New York), joints in two series, intersecting each other at nearly right angles ... about 80°), run with remarkable regularity; probably due to torsional strains ... warping. In areas of massive or metamorphic rocks, while a principal series can ... other joints show no regularity. Observed strikes may be plotted over a wide ... lines intersecting at a common center like a clock-face, resulting in detection of ... strikes. The predominant joint is called a MASTER JOINT; the others, minor ... Joints are of great practical importance in quarrying and in mining.

16. Minerals and Localization of Ore Deposits

Ore minerals are primary and secondary. The PRIMARY are those ori deposited in forming an ore body; the SECONDARY are produced by alt of primary minerals under certain conditions. Except aluminum, iron, ganese, chromium, platinum and tin, all primary ore minerals are sul arsenides, sulpharsenides, sulphantimonides, or similar compounds. Sul are of chief importance. Though secondary minerals are largely ox compounds, they also comprise a few very important sulphides.

The importance of the distinction lies in the following relations to the surface. G waters stand at varying depths, depending on local rainfall, rock texture and loc logical structure. Between ground-water level and the surface, is a zone cal Posepny the vadose zone, by Van Hise the zone of weathering, through which t dizing and dissolving rain waters freely descend. Within this vertical range, sul become oxidized to sulphates, and pass extensively into solution. Migrating dow the solutions merge into the standing and protecting ground-waters, and often p tate their dissolved metals in a zone of SECONDARY ENRICHMENT, at or near g water level. The reaction is especially important in copper mines.

Gangue minerals comprise quartz, calcite, fluorite, barite, rhodochr rhodonite, and admixed minerals of the country rock. Decomposition or ation under influence of thermal waters gives rise to much sericite, kao and related species.

Localization of ore deposits. Ore deposits resulting from processes outlined are developed where circulating mineral-bearing solutions find favorable places t cipitate their contents. One method of classification is to arrange in a logical s the favorable geological places for this reaction. For the formation of some kinds deposit, however, circulating solutions are not required. Ores may crystallize d from molten magmas, and, either by sinking in the fluid mass because of higher s gravity, or for some reason not well understood, may enrich the rock mass to the re ments of mining. Again, and in contrast with the reactions above indicated, m waters in streams, or by wave action, may liberate and concentrate heavy miner sedimentary deposits, to the point of profitable mining. Again, in residual dep heavy and resistant minerals may be left behind in a concentrated condition by re of products of weathering. In a few cases, chiefly iron ores, the processes of sed tation, or associated precipitation, have given rise to bedded ore deposits. Expe shows, therefore, that it is difficult consistently to classify ore bodies on any one of subordinate principles. But, as compared with old-time schemes based on shap broad principle of MODE OF ORIGIN has become increasingly important. In the foll classification, the endeavor has been to pass from igneous phenomena, pure and si to surface reactions not connected with igneous phenomena, emphasizing especiall places where ore bodies originate.

17. Classification of Ore Deposits

I. Primary magmatic origin.

(a) Masses produced by crystallization and segregation in cooling and soli ing igneous magmas: titaniferous and non-titaniferous magnetites, chro nickeliferous platinum, and probably sulphides of iron, nickel, and copper. A dikes and sheets of igneous magnetite are known.

II. Deposited by emissions from cooling and solidifying magmas.

(a) Various of the nature of pegmatites, varying from the mineralogy of gra to [illegible] with tourmaline, fluorite and minerals contai [illegible] rare elements, and exception [illegible] between dikes and veins; sometimes [illegible]

[illegible] by emissions from an [illegible] such as: garnet, d

...ntonite, vesuvianite, epidote; also of magnetite, specular hematite, ... of iron, copper, and less often of other metals.

... **Deposited by circulating ground-waters.**

... Deposits in or along faults, with greater or less replacement and im... of the walls; often called "true fissure" veins. They vary from the ... an open and clean-cut fissure, to impregnation and replacement of ... faults of small individual displacement.

... Saddle-reefs: precipitations of quartz or other minerals, at crest and be... layers of an anticline, and extending with diminishing thickness for ... but usually moderate distances down its flanks. Inverted saddles ap... synclines. Apparently arching of the strata has aided precipitation.

... Deposits in joints with greater or less replacement and impregnation of the ... often called "gash veins," because limited to a single stratum or sheet.

... Impregnations of volcanic agglomerates in the conduits of extinct ex... volcanoes.

... Impregnations with greater or less replacement of permeable rocks, ... amygdaloids, volcanic tuffs and breccias, open-textured sandstones ... conglomerates, autoclastics, etc. Supply conduit may be obscure.

... Replacements of limestones, calcareous shales or other beds, which have ... to circulating ground-waters. Supply conduit may be obscure.

... **Deposited or concentrated by aid of surface waters.**

... Surface precipitations, which may later be involved in stratified series. ... ores.

... Resistant or insoluble minerals, concentrated as a residuum by weather... removal of the matrix. Residual deposits. Cuban brown hematites.

... Placers or concentrations of heavy minerals in sands and gravels by ... moving water. Gold placers. Stream tin.

... above definitions are self-explanatory, and will receive no further comment. ... detail will be found in textbooks (22).

18. Iron Ores

... **ores minerals are chiefly productive** of iron: limonite (brown hematite, ... $2\,Fe_2O_3 \cdot 3\,H_2O$, Fe 59.8%; siderite (carbonate, spathic ore) $FeCO_3$, ... hematite (red and specular) Fe_2O_3, Fe 70.0%; magnetite (magnetic ... Fe_3O_4, Fe 72.4%. Associated with limonite, but less common, are ... ferric hydrates, as: turgite ($2\,Fe_2O_3 \cdot H_2O$); goethite ($Fe_2O_3 \cdot H_2O$). ... silicates may also occur, as: chamoisite (hydrated ferrous aluminum ... thuringite (hydrated ferrous or ferric aluminum silicate); greenalite ... ferrous silicate). Siderite may have its iron partly replaced with ... and calcium. With brown hematites, manganese minerals are not ... Pyrite (FeS_2) may appear with all the ores, and, when largely ... sulphur, may yield a residue possible of utilization for the poorest ... iron. Pyrrhotite (Fe_7S_8) is frequent with magnetites. Ilmenite ... is mechanically mingled with many magnetites. The objection... elements of iron ores are sulphur and phosphorus. Definite limits of ... merchantable grades of ore are variable, because of possible admixtures ... practice. In general, the less the better. In ores used for acid ... e.g. the permissible phosphorus maximum is 0.001 part of the per... of iron. Roughly, therefore, about 0.06% is the maximum with ...

... *ores and specular hematites* are the richest iron ores. In America lump mag... have in the past exceeded 65% iron, but today practically only magnetically

concentrated ore reaches this figure. Kiruna, Swedish Lapland, however, ca a great tonnage of this grade, even to American furnaces. Average of all iron in the U S in 1914 was not far from 50% iron. The grade will doubtless gradual Alabama Clinton red hematites run 36 to 37%. Some crude ore is even lo principal local supply of continental Europe, from the minette ores, averages a The nearness of good fuels, markets, mixtures, etc, determine limiting percenta

In the U S about four-fifths of the ore comes from Lake Superior region. order are the red hematites of Alabama and Tennessee, the brown hematite magnetites of Appalachian belt. Individual mines in Wyoming, Colorado, Mexico have fed the iron and steel plant at Pueblo, Colo. Magnetites will be in time on the Pacific coast for a future industry to be located presumably in Sound region.

Lake Superior iron districts. In order of productiveness in t Superior region are Minnesota, Michigan, and Wisconsin. Ontario productive range, and possibility of developing others. The ores of th are all in pre-Cambrian strata, now classified as follows:

Keweenawan: sandstones, basalt flows. Copper.
Huronian, Upper, Middle and Lower: sedimentary and some igneous roc ores in the sediments.
Laurentian: granites.
Keewatin: green schists, from ancient basic eruptives. Some sediments with

As now mined the ores are chiefly soft, partially hydrated hematit percentage in water not reaching that of limonite. They have been p by alteration of great beds of cherty carbonates of iron, of hydrated silicate, and of associated pyrite, under the general processes of wea Soft earthy masses of ore have thus resulted; of enormous volume, ac cheaply mined, and of relative purity as regards phosphorus and They occupy synclinal basins, troughs produced by intersection of dikes with each other or with impervious strata, or other minor place circulating and oxidizing meteoric ground-waters have been tempora structed in their flow. Besides soft ores there are lenticular bodies specular hematite, produced by metamorphism of ancient soft-ore bodi great bodies of jaspery or siliceous iron-bearing strata, of 35% and a iron, which, partly as concentrating ore, partly as low-grade lump or the gradual exhaustion of better grades, will be available for a long come. The grade is well above that of present European ores. Th originally formed beds precipitated at surface (Art 17, *j*). They becam in a stratified series, and afterward by weathering yielded residual (Art 17, *h*), some of which extend to great depths and are cases of se enrichment. Some have been metamorphosed to specular hematite, a magnetite. In northeastern Minnesota gabbros occur with igneous t ous magnetites, not yet shown to be valuable (Art 17, *a*) (23).

Clinton red hematites are next in productiveness. They appear of oölitic, often fossiliferous ore, associated with olive-green shales a ordinate limestones of the Clinton stage, at base of Silurian system. outcrop in S E Wisconsin, western Ohio, central Kentucky, western Ne south of Lake Ontario, and farther east at town of Clinton (whence their in Pennsylvania, Virginia, eastern Tennessee, Georgia, and Alabama. greatest development is in Alabama, where they form an inner terrace Red Mountain, in the Birmingham anticlinal valley. Good coking co limestone are near, so that low-cost pig can be produced even from 35 a ores. At outcrops the ores are siliceous; below ground-water level, t come basic. All are moderately high in phosphorus. They are p oölitic beds, precipitated in shallow estuaries, fed by iron-bearing d

Smyth). Although utilized in Tennessee and Georgia, they are most ... in Alabama. In time those in New York, Kentucky and Wisconsin ... to be of greater moment than now.

Brown hematites ("brown ores") of the U S are produced chiefly along that portion ... Appalachian mountains formed by early Paleozoic strata, and just west of the ... crystallines. They are products of weathering of ferruginous rocks, especially ... ores. In almost all the mines they must be freed of ochers and clays by washing.

Magnetites occur in two chief types of deposits. The commoner is a ... or pod-shaped mass, in gneisses, parallel with the foliation. They ... widely in the ancient Appalachian crystallines, but are most productive ... Adirondacks. The second type appears in the contact zones (Art 17, *c*), ... by intrusive igneous rocks on limestones or limey shales. The greatest ... of this type in the East is at Cornwall, Penn. The igneous rock is ... and the limestone, Cambro-Ordovician. In the West many such de- ... are known, in Utah (Iron Springs Dist), Nevada, California, and along ... west coast.

Oxides		*Native Metal*	
..., CuO.....	78.86	Native copper, Cu.....	100.00
... Cu_2O	88.80		

... distinction between primary and secondary minerals is more important ... copper than with any other metal. Some copper minerals appear in bo...h

groups. PRIMARY: chalcopyrite, bornite, chalcocite, enargite, tetr
(possibly native copper in Lake Superior mines). SECONDARY: ch
covellite, melaconite, cuprite, chalcanthite, brochantite, malachite,
chrysocolla, atacamite, and native copper. Possibly chalcopyrite and
are secondary in some cases. As a primary mineral lean copper-bearin
is very important, especially in intrusive rocks. When oxidized by r
waters in the vadose zone (belt of weathering), all copper-bearing s
yield some form of sulphate. This soluble salt, in deposits in siliceou
trickles downward until, in contact with some reducing agent, like py
copper is precipitated as chalcocite. This causes great concentration of
at or near ground-water level, termed SECONDARY ENRICHMENT. From b
copper-bearing sulphides, in regions of abundant rainfall, as at Ducktow
an upper zone or GOSSAN of brown hematite results, which may form an i
Below this, near ground-water level, a belt of rich chalcocite (black ore)
containing most of the copper once distributed throughout upper par
posit. Still lower are unaltered, primary sulphides. In a comparativ
region, when copper-bearing sulphides, usually in form of cupriferous
are disseminated in intrusive igneous rocks, or quartzites, or schists
may be crushed or rendered open-textured along a zone of moveme
scending waters of the vadose zone develop an upper leached belt, unde
a chalcocite-bearing section of maximum richness; and below this is a
secondary enrichment. Thus have originated the disseminated copp
now being extensively mined in the southwest. If oxidizing reactions
open-textured tuffs, or contact lime silicates, chrysocolla often results,
of chalcocite; if in presence of limestone, the blue and green carbona
cuprite are characteristic products. In North America most of the cop
duced comes from chalcocite.

Examples of copper deposits (letters in parentheses refer to Classi
Art 17).

A. Bodies of copper-bearing sulphides, chiefly chalcopyrite o
copper-bearing pyrite in igneous rocks (*a*). Chalcopyrite may be as
with a nickel-bearing sulphide, pentlandite, and with pyrrhotite, in b
trusives (Sudbury, Ontario). Lean copper-bearing pyrite of igneous i
masses, usually monzonites, requires secondary enrichment for profitab
ation (Bingham Canyon, Utah, and near Ely, Nevada).

B. Irregular masses of copper-bearing sulphides in contact zones
associated with lime silicates. Secondary enrichment, incident to oxidati
be necessary to increase percentage to mining requirements. Various min
of deposit may be associated. Bisbee and Morenci, Ariz, are best illust

C. Veins along faults, with greater or less replacement and impre
of the walls (*d*), as at Butte, Mont, where walls are granite. Innu
other veins are known in all parts of world.

D. Lenticular or pod-shaped bodies of pyrite or pyrrhotite, with
pyrite (usually of later introduction). The lenses favor schists or slat
lie parallel with the foliation. These rocks may be sheared eruptives, or
sediments (Ducktown, Tenn, and many ore bodies along Appalachians).
examples appear in foot-hills of Sierra Nevadas, Cal. Rio Tinto, Spain,
haps the largest body yet discovered.

The ore bodies were probably originally veins (*d*) parallel to structural planes
rocks, and subsequently pinched into lenses by pressure. The type called "Ki
may be of sedimentary origin or introduced as veins and pinched by pressure. So
been considered igneous intrusives, as at Sulitelma, Norway, and Bodenmais, Bav

Native copper in nodules, sheets, minute scales, and sometimes large masses, in amygdaloidal basalts, and associated conglomerates (*h*). Point, Michigan, is chief example. Introduction of the copper is a subject, whether a product of expiring igneous activity, or of circ- meteoric and connate waters.

Impregnations of sedimentary rocks with sulphides or their oxidized often deposited on organic remains (*h*). Mansfeld, Germany, is best example, where a black shale, with abundant organic remains, is im- with copper minerals for a width less than 1 ft, but over a great It is uncertain whether the copper was precipitated from Permian sea- along with the sediments, or introduced by circulating ground-waters after sediments were deposited. Triassic strata of the U S have many impregnations, mostly small.

percentage of copper for successful mining depends on widely varying conditions. copper rock, on Keweenaw Point, Mich, yielding only 0.65% (13 lb per ton), treated successfully. The disseminated chalcocite of Bingham Canyon, Utah, ed average assays over 3 months' periods as low as 1.3%, with approximately h recovery. Raw smelting ores, of slightly above 2% and with little aid from metals, have been worked at Ducktown, Tenn. In early days in western U S, to 20% were frequent in oxidized and enriched parts of deposits. Last quan- 100% ore are now reported from S E Congo State, Central Africa. To be valu- low-grade deposits must be of great size (25).

20. Lead and Zinc

Lead. Following minerals constitute the common ores of lead: galena, 86.6% lead; anglesite, $PbSO_4$, 68.3%; cerussite, $PbCO_3$, 77.5%; pyro- 3 $(PbO \cdot P_2O_5)\,PbCl_2$, 76.2% (much rarer than the others). Other ds sometimes appear in small amount, as wulfenite, crocoite and

na is the chief primary lead ore, of which others are oxidation products. ently associated with zinc blende and pyrite. All lead ores are com- in limestones than with other wall rocks. Many lead ores carry silver mercial amounts, especially in regions characteristically productive of metals. Gold is a rarer associate. The oxidized product of galena is erussite than anglesite. All oxidized ores are mingled with limonite g degree, and with silica and earthy minerals from alteration of wall Lead and zinc can best be discussed together.

Zinc. Following minerals constitute the common ores of zinc: sphalerite or de, ZnS, 67% zinc; calamine, $2\,ZnO \cdot H_2O \cdot SiO_2$, 54.2%; smithsonite, 52.1%; willemite, $2\,ZnO \cdot SiO_2$, 58.6%; zincite, ZnO, 80.3%; frank- $(Fe,Mn,Zn)O(Fe,Mn)_2O_3$, variable, about 6.0%. Willemite, zincite and e are so exceptional in their occurrence in northern New Jersey as to group by themselves.

lende is the almost universal primary mineral; calamine and smithsonite are its products. The latter two are often inseparably mixed, and together are known as "zinc" in Europe. "Dry-bone" is a local name in Mississippi Valley, the oxida- products suggesting old bones. (The significance of the names calamine and smith- England is the exact reverse of the American meaning, smithsonite being used silicate.) The oxidized compounds are characteristic of the vadose zone. coat bedrock beneath cap of residual products. The deposits are summarized with lead alone to those with zinc alone. Intimate mixtures of both ores afford great metallurgical problems today. Neither lead nor zinc deposits have been immediate association with igneous rocks, such that a direct igneous origin could ed to them. They obviously reach their places of precipitation in solution.

Examples of lead and zinc deposits. (Letters in parentheses re Classification, Art 17.)

A. Disseminated and sometimes coalescing deposits of galena associated sulphides, in sedimentary strata. The galena impregnates th sediment; believed to have been introduced in solution, and to have re preëxisting minerals; source is conjectural (*h* and *i*). In S E Missouri, th American source of lead for lead alone, Cambrian limestones are impreg

Near Laurium, Greece, galena replaces limestones involved with mica schis Leadville, Colo, Carboniferous limestone has been replaced with silver-bearing pyrite, manganese compounds and sometimes zinc blende, along under sides of rhyolite-porphyry ("white porphyry"). Extensive oxidation developed carbona for the early miners. Galena may yield to zinc blende in amount. In Belgium, I burg, and near Aix-la-Chapelle, huge subordinate lead ores have been mined vonian and Carboniferous limestone along great faults. Zinc blende was doubtl original mineral. In Silesia the zinc and lead ores are in Triassic limestones.

At Commern, Germany, knots of galena are disseminated in Triassic sandsto Cœur d'Alene district, Idaho, silver-bearing galena, with siderite, appears in bodies in pre-Cambrian quartzite, along or near extensive faults. Zinc blende ha met in some mines; copper ores in a few others. Siderite seems to have first re the quartzite, and then yielded to galena. The reaction is much the same as with c limestones.

In S W Missouri zinc blende and subordinate galena impregnate brec chert, interbedded in Lower Carboniferous limestones.

B. Galena, zinc blende and associated sulphides in joints ("veins") and related cavities (*f*). In S W Wisconsin and neighboring of Upper Mississippi Valley the Ordovician "Galena" limestone has nun vertical gash veins, with horizontal "runs" and inclined "pitches," cont galena, zinc blende, marcasite, and calcite.

C. Galena and zinc blende in fissure veins, often together, often sep usually with other sulphides (*d*). Precious metals are frequently assoc Such deposits are world-wide, and in all kinds of wall-rocks.

D. Lenticular deposits containing willemite, franklinite, subordinate z and many lime silicates, now folded in pitching synclinal troughs in pre-Cam limestones. It is difficult to classify these deposits. Their zinc-bearing mi are unique. The mineralogy suggests contact zones (*c*), but the actual morphosing igneous rock is not apparent.

In recent past, the price of lead has varied from extreme minimum of 3¢ per maximum of 5¢, ruling in late years not far from 4¢. Each per cent in a ton means roughly a value of 80¢, of which the miner may expect about 40¢. Z spelter rules about 1¢ above lead for ordinary brands, and 2¢ above for brands cally free from lead, antimony or arsenic. Each per cent of ordinary spelter in of ore means roughly $1, of which the miner receives about 50¢. Possibilities of n and concentration may be estimated on above basis.

21. Silver and Gold

Though deposits are known containing either gold or silver alone, metals are generally associated and must be discussed together. Both ar tensively obtained in connection with copper and lead. Lead ores are called "wet ores," because metallic lead, freed in smelting, acts as a solver the precious metals, the distinctive ores of which are called "dry ores." desilverization for base bullion, electrolytic refining for copper, and the stitution of cyanidation for amalgamation, have greatly facilitated treat of silver and gold ores.

Silver-bearing minerals: argentite ("silver glance"), Ag_2S, 87.1% silver; [illegible] $AgFe_2$, 62.8%; proustite ("light ruby ore"), Ag_3S_3As or $3\,Ag_2S \cdot As_2S_3$, pyrargyrite ("dark ruby ore"), Ag_3S_3Sb, or $3\,Ag_2S \cdot Sb_2S_3$, 59.8%; [illegible]ite ("brittle silver ore"), Ag_2S_4Sb or $5\,Ag_2S \cdot Sb_2S_3$, 68.5%; cerargyrite ("horn silver"), AgCl, 75.3%; native silver, Ag, 100%.

Silver almost always contains at least a trace of silver, which probably [illegible] as an isomorphous sulphide, but not appearing separately in polished [illegible]. Silver is a component of certain varieties of tetrahedrite, and in this [illegible] often found in copper ores.

[illegible] probably enters as a base into other copper minerals. Silver is sometimes found in [illegible] rarely in pyrite. Modern silver production is chiefly in connection with [illegible] metals. Cerargyrite and native silver are habitually secondary minerals, resulting [illegible] alteration in the vadose zone of other minerals mentioned above, or from silver-[illegible] base-metal minerals. Argentite probably is sometimes secondary; it certainly [illegible] primary. The others are generally primary.

Gold-bearing minerals: calaverite, $AuTe_2$, 44.5% gold; sylvanite ("graphic [illegible]"), $(Au,Ag)\,Te_2$, variable; native gold, alloyed with silver, etc, vari-[illegible] Gold most commonly occurs in quartz veins, both as native, and as [illegible] and wires mechanically mixed in pyrite. It may be set free by oxidation [illegible] removal of the pyrite. It also accompanies mispickel, chalcopyrite, and [illegible] galena. In some of these minerals, when the ores are refractory, it may [illegible] as an involved telluride, or as a bismuth compound (Richard Pearce). [illegible] tellurides of gold (a number of rare mixed tellurides of gold and other [illegible] are not mentioned above) are primary minerals. On oxidizing and [illegible] of tellurium, they yield extremely fine particles, not readily panned and resist-[illegible] amalgamation; called "rusty" gold. Gold, presumably as chloride, some-[illegible] descends in solution from oxidized portions of veins containing manganese [illegible] oxids, and is reprecipitated at or near water level. Presence of calcite may [illegible] here with the reaction (7). The high sp gr and resistance of gold to natural [illegible] cause greatly favor the formation of placer deposits.

[illegible] American writers sometimes classify precious metal deposits into an older series, in [illegible] Mesozoic age, and a later series. The great silver-gold veins associated with mountain [illegible] igneous and igneous outbreaks, at close of the Cretaceous and in the opening Tertiary [illegible] period can thus be distinguished from older ones. Each group can then be subdivided [illegible] associated minerals, of which a series of subtypes can be established. Other writers [illegible] placed less emphasis on variations in time and mineralogy. Admitting some [illegible] characteristic mineral associations, which might make possible finer subdivision, the following [illegible] large types are permissible (see Classification, Art 17).

Predominant silver. A. Fissure veins, with distinctively silver min-[illegible] in quartz gangue, often amethystine and associated with manganese [illegible] and some calcite. Galena, zinc blende, pyrite and copper minerals, [illegible] very subordinate. Many great veins of Mexico, as at Pachuca, Real del [illegible] and Guanajuato, exhibit these characters. The Butte silver veins are [illegible] but now, in instances, tend to develop copper in depth. In general, [illegible] is the chief source of silver (*d*).

B **Fissure veins yielding silver with little gold,** in association with galena, [illegible] blende, copper minerals, and pyrite, in gangue of quartz, calcite, barite, fluor-[illegible] or several (*d*). Veins of this mineralogy are world-wide in distribution.

C **Native silver and minor silver minerals,** with arsenides of cobalt and [illegible] in shrinkage cracks or fissures involving slight displacement (*d* and *f*). [illegible] Ont, is best example, where veins are predominantly in Huronian con-[illegible]rate, associated with a diabase sill, which has some veins, and Keewatin [illegible] schists, which contain a few.

D. Impregnations of porous rocks, sandstones, tuffs, etc, with ar cerargyrite, and native silver; supply fissures obscure; some copper m may occur. (Silver Reef, Utah, Silver Cliff, Colo.)

E. Impregnations and replacements of crushed rocks along (silver-bearing galena in Cœur d'Alene, Idaho, Art 20, A).

F. Replacements of calcareous rocks with silver-bearing galena an ciated sulphides. Leadville, Colo. (See Art 20, A, for other cases.)

Predominant Gold. A. Fissure veins containing native gold, al mechanically mixed in pyrite and much rarer base-metal sulphides, in gangue. Gray, greasy-looking quartz seems to accompany best values common association of quartz with gold makes this type of world-wide bution. Veins appear most frequently in schists, slates, or other metan rocks, and in association with intrusive rocks, of which granite is comm

B. Impregnations and replacements of open-textured rocks wit bearing pyrite. The "banket" of gold-bearing conglomerates of Transv chief producers today, is the best example.

C. Saddle-reefs, or arch-like deposits of gold-bearing quartz at cr anticlines (*e*) (Bendigo, Victoria, and gold reefs of Nova Scotia). Sadd may succeed one another in depth. Slates or slaty schists are commo rocks.

D. Veins carrying gold tellurides. At Cripple Creek, Colo, th associated with an eroded Eocene volcano, often favoring neighborh minor dikes of phonolite and basaltic rocks, with which volcanic activity Purple fluorite is a characteristic associate. In Boulder Co, Colo, veins gneisses; at Kalgoorlie, Western Australia, in amphibolites; in Hung tered andesitic rocks, called propylites. Once considered extremely rare rides have been very productive in Cripple Creek and Kalgoorlie.

E. Lateral impregnations and replacements of calcareous shale tellurides along supply fissures, called verticals. Example, so-called "Pot or "refractory ores," of the Black Hills, S Dak, the walls of which Cambrian age.

F. Contact zones, on the border of intrusive igneous rock and lim containing gold-bearing mispickel in lime silicates (Nickel-plate mine, The usual contact zone of this type carries copper sulphides, with a gold (Art 19, B).

G. Placer deposits of gold-bearing gravels, which may be: residua weathering of rocks *in situ;* river gravels in active streams; river gra abandoned and often buried channels; alluvial fans; sea-beaches with surf; sea-beaches now elevated and inland. Gold in streams favors where current has been checked, as the inside of bends; junctions of tribu heads of quiet reaches. Gold favors gravel next the bedrock, or next a bedrock" of clay, but fine particles may be generally distributed in a thi tical section. Magnetite, zircon, garnet, and various resistant, heavy m are characteristic associates, yielding "black sands" (26).

22. Minor Metals

Aluminum is obtained today from bauxite, representing a series from Al_2O to $Al_2O_3 \cdot 3(H_2O)$, which is treated electrolytically in a bath of cryolite ($3\,NaF$ Bauxite is developed by weathering of aluminous rocks, and may appear as a r product. It is probably also produced by solvent action of sulphuric acid, from

...rite upon aluminous rocks, such as shales. The resulting acid solution of alu... sulphate may be neutralised by limestone, with precipitation of aluminum hydrate, ... may then form concretionary masses. In America bauxite is largely produced in ... where last named reaction is believed to explain its occurrence. In Arkansas, it ...ciated with syenitic eruptives, to the alteration of which, perhaps while yet hot, its ...on is attributed. Cryolite is commercially obtained only on west coast of Green... where it constitutes a large, flat vein in gneiss. Siderite, galena, zinc blende, and a ...ter minerals are sparingly mingled with it.

Antimony is obtained from its sulphide, stibnite (Sb_2S_3); sometimes from the oxide, ...timonite (Sb_2O_3); and as an alloy from antimonial lead ores. Characteristic occur... of stibnite is in quartzose veins, but some less regular deposits in sandstone have ...n recorded. The industry is small.

Arsenic is produced almost entirely as a by-product in smelting arsenical copper ores, ... enargite (Cu_3AsS_4). It is sold as oxide, but much more could be saved were ...e a market for it.

Barium is chiefly consumed as the sulphate ($BaSO_4$). Barite characteristically ap... in veins in limestones; is also a frequent gangue with lead and copper ores, re... of nature of vein walls. Chief output in U S comes from residual clay deposits ... and Texas.

Bismuth is a rare by-product in lead-silver refining. A few districts, Telluride and ...e, Colo, produce small amounts of high-grade bismuth ore.

Cadmium is a minor associate of zinc, and whenever separated is a small by-product ...c metallurgy, or in treatment of zinc-bearing lead ores.

Cesium is a rare alkaline element of much the same associations as rubidium.

Cerium, with didymium, erbium, lanthanum, thorium, and yttrium, constitutes a ... called the cerium group of rare earths. Their compounds, especially those of ...m, have incandescent properties when heated, for which purpose they are sought. ...y are obtained as phosphates in monazite and xenotime, and are characteristic of ...ites. They may appear in normal granite. Being resistant and heavy, monazite ...ains have accumulated in placers in the drainage of pegmatite and granite ... the Carolinas; also on sea coast of Bahia, Brazil. Relatively high percentages ...ium are desirable.

Chromium ($FeO \cdot Cr_2O_3$), sometimes $(Fe \cdot Mg)O \cdot (Cr \cdot Al \cdot Fe)_2O_3$, is a characteristic ...ite of richly magnesian, basic igneous rocks, usually altered to serpentine. The ...ite is believed to be a direct crystallization from molten magma. It forms irregu... sometimes large, distributed masses, and being extremely resistant may be freed ...concentrated as a residual product in weathering. Commercial chromite should ...ain at least 40% Cr_2O_3.

Cobalt forms a variety of arsenides and sulphides, practically always in association ...kel. Linnæite (Co_3S_4), smaltite ($CoAs_2$), cobaltite (CoAsS), and the oxidized ...ty erythrite or "cobalt bloom" ($Co_3As_2O_8 \cdot 8\,H_2O$). Once the object of a small ...metallurgy and produced as a by-product in the larger nickel industry, since ...overy of the rich silver-cobalt veins, at Cobalt, Ont, cobalt is over-supplied.

Didymium (see Cerium).

Erbium (see Cerium).

Iridium see Platinum).

Lanthanum (see Cerium).

Lithium is obtained from 2 silicates: lepidolite, the lithia-mica ($LiK \cdot Al_2O_3F_2Si_3$) with ...0. 2 to 5%; and spodumene ($LiO \cdot Al_2O_3 \cdot 4\,SiO_2$) with lithia 7.5%. Both are ...ite minerals, occurring mainly in Black Hills, S Dak. Lepidolite is more easily

Magnesium is chiefly used as the earthy carbonate, magnesite, a refractory material. ...ite favors association with serpentines, in the alteration of which it is formed ... Hungary, Greece, and California are chief producers.

Manganese has one principal ore, pyrolusite (MnO_2) with Mn, 63.2%, and
minor ores. Other forms of oxides, *viz:* braunite (Mn_2O_3); hausmannite (M
psilomelane, hydrated oxide of variable composition; franklinite (Art 20). I
logical relations of its ores, manganese is similar to the brown hematites (Art 6).
ores are usually residual products of weathering, and are found as nodules in cla
masses on surface. They should be relatively low in phosphorus, for use in s
eisen, and not too high in silica (27).

Mercury has one chief ore, cinnabar (HgS), with which a little native metal
associated. Cinnabar appears in veins with quartz, calcite, altered wall-rock and bi
It may also impregnate porous beds, such as sandstones. In practice mercury is
quicksilver or "quick." Its importance has declined with the increased use of c
solutions for extracting gold and silver.

Molybdenum is obtained from molybdenite (MoS_2). Wulfenite ($PbMoO_4$)
tracted some attention. Molybdenite is a pegmatite mineral, sometimes seen in
quartz veins. It is rather frequent in contact zones, produced from limestones
trusive igneous rocks, but only in small amount.

Nickel has 3 varieties of ores: (*a*) sulphides and arsenides (millerite,
niccolite, NiAs) and related minerals, all of small moment today; (*b*) pen
ite, $(NiFe)_7S_8$, or some similar atomic ratio, the nickel, iron and sulphur
each about one third. (Although nickel was formerly thought to replac
in pyrrhotite, it is now proved to be in mechanically intermingled pentla
(*c*) a series of hydrated silicates of nickel and magnesium, somewhat ana
to serpentine in general composition and forming veins in serpentine,
duced in the alteration of very basic igneous rocks.

The nickel industry today is practically limited to 2 localities. At Sudbury, C
vicinity, pentlandite with pyrrhotite and chalcopyrite are concentrated at botto
huge intrusive sheet, which varies from norite at the base, where the ores appear,
micrographic granite at its upper surface. The sheet is folded into a huge ba
miles across, and is buried in center beneath overlying sediments and volcanic
ores favor embayments in the underlying older rocks, and one offsetting dike
outer periphery. The underside of sheet dips inward at 60°, and is impregnat
nickel and copper ores up to widths of 100 or 150 ft. The gangue is self-fluxin
ore bodies are generally classed under *a*, Art 17, but the 3 sulphides seem to have
lized in serial order, and at times to have undergone some redeposition. The h
silicates of nickel are found, in workable richness, in the serpentinous district
Caledonia. They constitute veins, and are the second important factor in the
supply (28).

Osmium is a characteristic associate of platinum, in the placers of which
source, iridosmine, is found, in scales or scaly nuggets and "colors."

Palladium is a characteristic associate of platinum in placers, and in the fe
where platinum has been discovered in copper ores. In latter case careful as
necessary to avoid mistaking palladium for platinum.

Platinum appears in metallic grains and nuggets, more or less alloyed wi
palladium, and rarer metals of the platinum group. It is characteristically as
with peridotites and pyroxenites, in which it is a direct crystallization from the
fused magma. Platinum is frequently intergrown with chromite. Aside from
alloys, its one compound is sperrylite ($PtAs_2$), a minute associate of the Sudbury
copper ores, and rarely elsewhere (29).

Potassium is treated as a saline (see Non-Metallic Minerals).

Radium is an extremely rare associate of the more abundant uranium, from t
erals of which it is separated (see Uranium).

Rhodium is a minor associate of platinum.

Rubidium is a rare alkaline element, associated in minute amounts with lith
lepidolite and other lithium minerals.

Ruthenium *is* an extremely rare associate of platinum.

...um is treated as a saline (see Non-Metallic Minerals).

...ium is obtained from the sulphate, celestite ($SrSO_4$), occurring like barite, but ... (see Barium).

...um (see Cerium). Thorianite is also found commercially in Ceylon and ...

...n as one ore, cassiterite (SnO_2), and one rare sulphide, stannite. Cassiterite is al... associated with granites and pegmatites, or veins closely akin to pegmatites. ...ering and erosion of these, being heavy and resistant, it is concentrated in ... as pebbles and finer particles, called stream tin. Cassiterite is obtained both by ... and placer working. It has been observed associated with rhyolites. Tin ... obtained from some Bolivian silver-bearing veins.

...um appears in the titaniferous magnetites, in which it has hitherto been a dis... to the iron. Varieties extremely rich in titanium, and pegmatitic veins or ... containing rutile (TiO_2), are now mined as a source of ferro-titanium. Titaniferous ... are intergrowths of magnetite and ilmenite, often extremely intimate.

...sten is obtained from several tungstates, *viz.* wolframite, $(FeMn)WO_4$; huebner... $MnWO_4$; scheelite, $CaWO_4$. It is a characteristic mineral of pegmatite and veins ... to pegmatites. Scheelite appears at times in gold-bearing quartz veins.

...nium has gained great prominence as the associate of radium, but has also uses of ... Pitchblende or uraninite, $(UPb_3)_3U_2O_9$, the earlier and still prized source, is a ... characteristic mineral of pegmatites and related veins. A series of phosphates, ...ite, autunite, etc, have similar geological relations. Carnotite, a vanadate, $K_2O \cdot V_2O_5 \cdot 3\,H_2O$, with 15 to 18% vanadium oxide, is found impregnating ... in western Colorado and eastern Utah, and is now much sought for radium.

...nadium is a minor component of titaniferous iron ores, and of the uranium-bearing ... and, in a series of vanadium sulphides and their oxidized derivatives, appears ... veins in Peru.

...rium (see Cerium).

...conium has one mineral, zircon ($ZrSiO_4$), an associate of granites and other feld... rocks and pegmatites, from which on weathering it is freed and concentrated in ...

NON-METALLIC MINERALS

Here is included a miscellaneous series with no fundamental relations; hence, ... alphabetically. The carbon series is the most important (30).

28. Abrasives; Asbestos; Asphalt

Abrasives. Corundum and emery (emery is a mixture of corundum, spinel, magnet... and other hard and heavy minerals) are found in two principal geological relations: ... crystallizes from rare igneous magmas containing excess of Al_2O_3 above re... ments of ordinary rock-making minerals. Nephelite-syenite, in Ontario, and peri... in North Carolina, fulfil these conditions. EMERY is commonly found at igneous ... or where inclusions of aluminous sediments are involved and partly digested in ... as rocks. A vein or bed at Chester, Mass, containing emery in metamorphic rocks, ... interest. GARNET, either in hornblende schist, as in the Adirondacks, or in mica ... as at Reading, Conn, is a minor abrasive. Crushed, angular fragments of QUARTZ ... used for sand-paper. DIATOMACEOUS EARTH and decomposed chert (TRIPOLI) are soft ... WHETSTONES are made of gritty slates, which sometimes owe their "tooth" ... garnets or other hard minerals; or of novaculite, a fine-grained siliceous rock ... the solution and removal of minute rhombs of calcite have left sharp-edged ... Coarse varieties are sandstones, or sandy schists, in which are set rutile, garnet, GRINDSTONES are made of sandstones sufficiently friable not to wear smooth (31).

Asbestos of commerce, a variety of serpentine, called chrysotile, appears as veins ...-fibers in some serpentine districts (most important is in southern Quebec). ... grades appear along slips in the serpentine and in the mass of the rock. Some

believe the Canadian asbestos to be a deep-seated alteration product of basic rocks; others that it is developed from serpentine in fissures near intrusive aplite, a variety of granite (32).

Asphalt (see Carbon Minerals).

24. Building Stone; Clay; Limes; Cements

The granite industry is mainly developed along Atlantic seaboard; secondarily Wisconsin, Missouri, and California. Among igneous rocks, granite breaks best quarry. When of good grade, it is homogeneous in texture, though sometimes spoiled from black inclusions, local coarse crystallizations, and development of gneissoid ture. SANDSTONES are widely quarried. The "brownstone" of eastern U S is a sandstone, from Longmeadow, Mass; Portland, Conn; Avon, N J; Hummelstown Harrisburg, Penn. "Bluestone," of Hudson River region, is a Devonian argill sandstone, specially adapted to flagstones, curbing, sills, and lintels. Potsdam red stone or quartzite is Cambrian; quarried on western side of Adirondacks. A stone of nearly the same geological horizon is produced on south shore of Lake Su Medina pink sandstone of the Silurian is extensively obtained along the Erie between Rochester and Lockport, N Y. Cleveland or Ohio sandstone is a gray or blue stone, of Mississippian (Lower Carboniferous) age, developed in outskirts of land. LIMESTONES. Preëminent is the Indiana or Bedford oölitic stone, of Mississ (Lower Carboniferous) age, which outcrops in an extended N and S belt in S W In MARBLES, of Cambrian and Ordovician age, are extensively developed along the of Western Vermont, Eastern Tennessee, and Georgia; of other age, in Colo. S appear in S W Vermont and neighboring parts of N Y, and in the Lehigh Valley, They are in less degree produced in Virginia, the Lake Superior region, and Newf land. Wales is a famous source of slate and of skilled workers in slate. SERPE is quarried in southeastern Pennsylvania and the neighboring parts of Maryland (3

Clays are of two kinds: residual, especially from weathering of limestone; and ported, which are the finest sediments of still water. Residual clays are comm south of the terminal moraine of Glacial epoch. They are impure and variable. T ported clays were extensively deposited by the floods which followed the melting of th tinental glacier. They are very abundant in the valleys of the Connecticut and H rivers, and are the basis of a great brick industry. Fireclay for refractory materials s be as free as possible from other ingredients than SiO_2, Al_2O_3, and H_2O. It is often beneath coal seams. In these relations fireclays are mined in Pennsylvania, Mary Ohio, and at Cheltenham, Mo. Other fireclays of Cretaceous age are developed at V bridge and its neighborhood, N J, and near Golden, Colo (34) (see also Sec I, Table V

Shales often possess properties which fit them for vitrified brick. They are ground, moulded, and hard-burned. They are useful for pavements, especially whe good rock is available for macadam.

Limes and cements. For quicklime, calcium carbonate should be pure, free coloring ingredients, such as iron compounds, and is preferred with little magnesium bonate. Silica and alumina together develop hydraulic properties, and injure " limes. Kilns are widespread and, for local use, any reasonably pure limestone ans Rockland, Me, is the principal American producing district. As limestones contai creasing amounts of alumina and silica, they develop hydraulic properties when bu and in varieties of special excellence afford natural rock cement. The crude sto called a "water-lime." Although important in former years, the natural cements given way to "Portland" cement, which is an artificial mixture of limestone and cl shale, entirely under control of the chemist, and being therefore more uniform in pr ties. In Portland cement magnesia is kept very low, not over 2 or 3%. The Le Valley, Penn, is chief center of manufacture in U S, but plants are widely distributed

25. The Carbon Minerals

These embrace Coals and their relatives, and the Petroleum series, incl ing Natural Gas, Maltha, Asphalt, and Asphaltites.

Coals and their relatives are vegetable remains so preserved in sediment strata as to become progressively enriched in carbon. They begin as some f

...y tissue, perhaps also in part spores, algæ, and resins; under conditions ...ded oxidation they pass toward a theoretical limit of nearly pure carbon, ...ally to mineral ash. Cellulose, the principal original contributor, is ... approx, C 50%, H 6%, and O 44%), but there was always also a little ... mineral matter in original deposit. If vegetable tissue accumulates ... protecting layer of water, oxidation is retarded and relative enrichment ...es ensues. On subsidence of the land, or, in case of lakes and swamps, as ... heavy floods, sediments bury the accumulated vegetable tissue. The ... process comprises several stages. PEAT is still brown; a visible aggregate ... leaves, etc; high in O and H and relatively low in C. LIGNITE is firmer, ...ick, but has a brown streak, and usually still shows evidence of vegetable ... less O and H than peat and relatively more C. Sub-bituminous coals ...ch lignites are a stage beyond typical lignite, but are not typically bitumi-... BITUMINOUS COALS (Sec 35) are black, solider, lower in O, higher in C, and ...ost possess coking properties. SEMI-BITUMINOUS and SEMI-ANTHRACITE ...passages to ANTHRACITE (Sec 34) in which the C is greatly enriched and the ...ard and firm. Still further stages toward graphite are known.

Table 5. Characteristic Chemical Composition of Coal Series

...r is also present in varying percentages, up to several units, and mineral ash ... ash.

...ls are analyzed commercially in 2 ways, proximate and elementary. In PROXI-...ATES, moisture, volatile matter, fixed carbon, ash and sulphur are usually de-...ed. Sample is dried, weighed, ignited until flames cease or for a standard time ... standard Bunsen burner, weighed, ignited again to consume the carbon; after ...duct is weighed for ash. Sulphur is determined in a separate sample. This ... shows if the coal is high or low in water; is high or low in volatiles; has a ... short flame; cokes or not; is high or low in ash; is sulphurous or not. These are ...st important points regarding a fuel. Dividing the percentage of fixed carbon ... percentage of volatiles gives the "fuel ratio," characteristic for each particular ...: anthracites give high, and richly bituminous coals low ratios. Ratios vary from ... 1. to about 30. ELEMENTARY ANALYSIS of a dried sample gives the C, H, O, N, S, ... It affords a better idea of the heat units in the coal, a matter of growing im-...ce each year, but does not indicate coking properties nor volatiles. It is known ... O in coals is already combined with C or H, and is as inert as ash, besides re-... the available C and H. Since H has a high calorific value, the necessary pro-... to yield H_2O with the O present is often called combined hydrogen; the excess, ...ee hydrogen. Relatively high values of the latter are esteemed.

Table 6. Characteristic Proximate Analyses

...	Moisture	Volatiles	Fixed carbon	Ash	Sulphur
...	20.22	52.31	24.52	2.95	.....
...	17.75	37.85	37.40	6.20	0.80
...minous	13.43	37.15	45.57	3.85	.....
...ous	1.26	30.11	59.62	8.23	0.78
...minous	1.23	15.47	73.51	9.09	0.70
...thracite	1.29	8.10	83.35	6.23	1.03
...ite	4.12	3.08	86.38	5.92	0.50

Table 7. Characteristic Elementary Analyses

	Moisture	C	H	O	N	S
Peat (air dried).....	13.60	40.78	5.55	30.95	1.40	0.58
Lignite.....	22.63	54.91	6.39	32.59	1.02	0.59
Sub-bituminous.....	11.05	59.08	5.37	21.52	1.33	1.73
Bituminous.....	3.36	68.69	4.84	11.49	1.54	1.01
Semi-bituminous....	1.53	82.87	4.76	4.99	1.68	0.65
Anthracite	1.97	91.40	2.81	1.83	0.21	0.71

Heat units are expressed as British thermal units (B t u), or as French (High-ash or high-oxygen coals give low thermal values. The usual range is as the peat being exceptionally good (Sussex Co, N J):

Peat	Lignite		Bituminous coal		Anthracit	
High	Low	High	Low	High	Low	H
8 260	7 204	10 143	10 242	13 790	12 047	14

Moisture in coal is a serious drawback, and varies so much in unprotected especially of lignites and sub-bituminous coals, that the sample, as soon as cut in t should be put into an air-tight glass jar, and analyzed as soon as possible afte unscrewed.

Classification. Many attempts have been made to classify coals, but for easte the scheme suggested by H. D. Rogers, State Geologist of Penn, about 1855, widely current:

Bituminous	Volatiles, greater than 18
Semi-bituminous	" 18 to 12
Semi-anthracite	" 12 to 8
Anthracite	" less than 8

More recent schemes are those of: M. R. Campbell, based on $C + H$ ratio, as sh elementary analysis; F. G. Grout, who employs ratios based on sum of volati fixed carbon of a proximate analysis, and the elementary carbon of ultimate a and D. B. Dowling, who employs what he calls the split-volatile ratio. All the greater attention to western lignites and sub-bituminous coals, which in earlie were practically unknown. Elaborate classifications are unimportant comme The B t u 's and the physical and coking properties are the essentials.

Geological associates of coal seams are almost always shales and stones. They often have a fireclay floor; are seldom associated with stones. A seam may be broken up into benches by a "parting" of shale, "slate" by miners. A parting may increase in thickness and separate a into 2 distinct seams. Seams may be cut out by old drainage channels, contemporaneous with the old swamp, or later and long after coal was fo Pot-holes and channels in Carboniferous coals were developed even i Glacial epoch and filled with gravel. Coal seams may be pinched by th ward bulge of a relatively plastic clay floor, and may have cracks filled clay gouge.

Coal seams are subject to faults and folds; are very often in syn ("basins"), left disconnected by erosion of intervening anticlines. Folds be violent, as in middle anthracite fields of Penn, and in Belgian and F areas. Coal seams are of all thicknesses from a fraction of an inch to feet. The thickest single seam, reasonably free from thick partings, rec

erica, is at Adaville, Western Wyoming, with 86 ft of clean coal (except parting of 1 in of sandstone). A thickness of 1 ft is ordinarily considered the minimum of workability.

increase of ash (20% ash is the usual commercial maximum) coals "bony" coals, then into "bone" and into bituminous shale or slate. matter may be minutely interstratified with thin layers of relatively or be invisibly mingled. If the layers are sufficiently coarse, crushand washing may greatly reduce the ash (Sec 34 and 35). In a cross-section good seam can be recognized: bright lustrous "glance" coal and dull, "splint" coal. The proportions vary; one variety may be in great There is a third variety, porous, tender, and often showing plant called "mother of coal" or "mineral charcoal." It affords an unplace of precipitation for gypsum, pyrite, and other undesirables. phur in coal is partly in pyrite, when half passes off in burning; partly in when all passes into the ash; and partly in sulphurous hydrocarbons. ing or other combustion, roughly one-half the sulphur passes off.

geological age coal ranges practically from Carboniferous period through Tertiary. is even reported in remote pre-Cambrian strata of Finland, but no seams of are yet known older than Carboniferous. The oldest seam in America is in sandstone series, of the Mississippian (Lower Carboniferous) strata of S W Alberta and elsewhere). The really important coals begin with the PennsylIn eastern half of North America, they range up into the Permian and even in Va and N C). In the western U S, coals range from early Cretaceous Eocene. The Laramie of Cretaceous and Eocene Tertiary are most productive. The are often lignitic, especially if in relatively undisturbed strata (36).

Petroleum series. Coals are residual accumulations; petroleums are evolved, move from their sources elsewhere for storage. The petroleum series embraces gases, liquids, and solids. The chemistry is very complex, but most the members belong to the marsh-gas or paraffine series of compounds, C_nH_{2n+2}. Up to C_4H_{10} they are gases at ordinary temperatures; from $C_{16}H_{34}$ they are solids. The gases are called natural gas; the liquids, petroleum; thick, black, tarry liquids, maltha; the solids at ordinary temperatures, of leathery character, asphalt; the brittle, coal-like substances, asphaltite; natural paraffines, ozocerite. Shales impregnated with bituminous matter called oil shales. They may be rich in paraffines.

Natural gases are chiefly CH_4 but have some higher members, with a little the olefine series C_nH_{2n}, more or less of H_2S, N, O, CO_2, and others rarer.

Petroleums include the liquids at ordinary temperatures. Some are of low some high. These characters are expressed in degrees Beaumé, a scale which 10° Beaumé is sp gr 1. Others are calculated by the formula: $\frac{140}{\text{sp gr}} - 130$. Light petroleums range from 35° B up. The heavy drop below 20° B. Lighter oils give higher percentages of illuminants and are the more valuable. Heavy oils have an asphalt base. Some oils contain sulphur compounds. Malthas are much rarer than petroleums, and have different asphalts are specially employed for paving; asphaltites for varnishes, etc.

Origin of petroleums. There are two radically different views: the inorganic (now largely held) and the organic. There is some support for the theory attributing hydrocarbons to igneous sources, but most geologists favor the organic explanations. These the original plant or animal matter in the sediments, by decomposition in the rock (Hunt); or distillation from internal heat (J. S. Newberry); or, the modern view, bacterial decomposition while freshly deposited, the hydrocarbons being later squeezed out of the shales and mud-rocks, by pressure of overlying accumulations, into porous beds for storage. In the latter way marsh gas, CH_4, certainly does develop, but oils remain to be demonstrated (Sec 1, Table VIII).

Storage in the rocks is better understood. The most extensive pools are found low, anticlinal folds, in which an impervious shale rests upon a porous sandstone c stone, so as to imprison the gas and oil; which, from some source of the hydroc rise through the heavier ground-waters and are finally caught beneath the crest. retically, and sometimes actually, there is an uppermost layer of gas, a layer ben oil, and a bottom layer of water or connate brine. Usually either gas or oil rests or Other deposits favor lenticular or pod-like bodies of sandstone in shales, apparen sand-bars, or similar accumulations. Prospecting is usually guided in recent ye the anticlinal view. The axes of anticlines rise and fall, and pools are thus n tinuous along their trend. A very gentle anticline or even a slight monocline may Pools sometimes seem to lie to one side of the observed anticlinal crest.

Geologically, the oldest gases and oils are tapped from Ordovician (or Lower Si strata, of which the Trenton limestone is very productive in Ohio and Indiana. In the Paleozoic, the Silurian (or Upper Silurian), Devonian and Carboniferous are all productive in the Eastern States. A sandstone at base of the Coal Measure boniferous) is very productive in Illinois, Kansas, and Oklahoma. Cretaceous stones carry oil in Wyoming;, and Cretaceous limestones are the apparent sou Mexican petroleum, even though tapped from overlying Tertiary beds. Variou tiary horizons yield oils in different parts of the world, but the Miocene is especiall In America are the following fields: Appalachian; Lima-Indiana (western Oh Indiana); Illinois; Mid-Continental, in Kansas, Oklahoma and northern Texas; in Louisiana and Texas; Mexican, in the coastal plain or tierra caliente, west of T and further south; and California. There are many smaller areas in Colorado, Wy Alberta, and Alaska. Trinidad is productive and Venezuela very promising. A Rumania, Baku on the Caspian Sea, Dutch East Indies, and Japan are the chi ducers, but some oil has also been found in Germany (57).

Maltha is a rather unusual product, but appears at times where oils with an as base rise to surface and lose their more volatile constituents. Maltha may impe porous sandstone.

Asphalt, a further stage in the process, may accumulate in pools, c pregnate porous sandstones or limestones. Sometimes oils have risen in fi and have changed with loss of volatiles to brittle substances, suggesting Illustrations: albertite, of N B; grahamite, of West Va; uintaite and wurt of Utah. Oils with a paraffine base have left behind the natural par ozocerite, in fissures in sandstone (Sec 1, Table VIII) (58).

Graphite is the final metamorphic stage of all carbon minerals. It a sometimes in pegmatite veins, but more often impregnates sandstones, s and crystalline limestones, from which it may be separated by concentr the light components (60).

98. Miscellaneous Non-metallic Minerals

Gems are objects of [illegible] but the geological relations are very diverse. Dia [illegible] in certain rocks, notably in very basic igneous rocks, in South Africa western Arkansas. They are also here obtained from placer deposits. Sapphire be in contact zones of components of an igneous dike as at Yogo, Mont. are pegmatite minerals, but the various emeralds may be in contact zones. Turquoi [illegible] and crystalline rocks, where copper salts have circulated. No [illegible] can [illegible] as the [illegible]

Graphite (see Carbon Minerals).

Gems (see Carbon Minerals).

Gypsum (see Salines).

Mica, in [illegible] occurs as a constituent of coarsely crysta pegmatites, but [illegible] and [illegible] amber are utilized, the f produced mainly in India and N Carolina, the latter in Ontario and Quebec prov Canada. [illegible] mainly as rectangular trimmed

... larger sizes bring higher prices). Demand for pulverized mica is amply sup- ... trimmings from sheet-mica mines. (*b*) Softness; the softer the mica the ... adapted it is for electric commutator insulation. (*c*) Freedom from inclusions, ... are generally iron minerals and diminish insulating properties. (*d*) Flexibility. ... a given mica can be ascertained only by submitting samples to a dealer. ... manufacturers are the largest consumers.

... isolated bodies of the ocean, cut off perhaps by a barrier cast up during a storm, ... thin beds of salt and their associates have been derived. Thick beds of hun- ... feet in section are difficult to explain in this way. A substitute explanation is ... Theory" of Ochsenius. A deep estuary is assumed to be isolated by a broad ... the open sea. Evaporation on the bar leads to the passage down inner side of ... heavy concentrated brine, until salt is deposited in the estuary's depths. Thick ... also be precipitated in salt lakes, in deep depressions without outlet, yet so ... to be fed by salt-bearing streams. Great Salt Lake is an illustration. Salt ... at Petite Anse, Louisiana, and elsewhere along Gulf of Mexico, appear in co- ... chimney-like form, crossing sedimentary strata as great cylindrical masses, ... are domes or mounds, and around which the beds turn up. These are best ... by uprising salt springs and the expansive force of growing crystals, which may

have thrust the strata aside and upward. The only important beds of potassiu yet discovered are in the Stassfurt region, western Germany. Beds of Na_2SO_4 infrequent in arid regions, and less often waters or even beds charged with Na_2C sodium and calcium borates, likewise occur in a few districts (as southern Ca and western Nevada), where local drainage contains these rare salts. The soils northern Chilean desert have become charged with sodium nitrate, as have the few other arid localities (42).

Borax is obtained, by chemical treatment, mainly from 2 minerals: bo occurring in fumaroles in northern Italy, and in dry-lake deposits in desert regions of the world; and colemanite (borate of lime) occurr bedded saline deposits in southern California. The latter, averaging boric acid, are now the principal source of borax in the U S, refineries at San Francisco, Cal, and Bayonne, N J.

Sulphur. In native state, sulphur is found in 2 types of deposit: (*a*) near volcanic craters, expiring or largely dormant. Emitted as vapor, s condenses on walls of cavities and impregnates porous tuffs and breccias. possible, but not highly probable, that SO_3 and H_2S when mingled hot r deposit sulphur. (*b*) In association with gypsum in sedimentary strata, Sicily, Louisiana, and Texas. The sulphur was formerly believed to from reduction of gypsum ($CaSO_4 \cdot 2\,H_2O$), by organic matter in circ ground-waters. There is at present a disposition to refer it to minute isms now known to secrete elementary sulphur, and to favor its precipi amid deposits of decaying organic matter, at bottom of certain bodies of Gypsum is a universal associate (43).

1. Clearing and Grubbing

Methods: (*a*) Grubbing; (*b*) burning; (*c*) blasting; (*d*) stump pullers.

Grubbing by hand. Tools: mattock, axe, round-pointed shovel, and long bar. Two men working on a single stump are more efficient than one man alone. If the large roots are cut in the fall and allowed to lie during the winter, the heavy frosts of the northern states will loosen the stump and materially assist the work of removal.

Burning stumps. The soil should be dug away, partly exposing the largest roots. Dry wood logs are piled about the stump, and kept burning until it and the larger roots are consumed. This method is especially adapted to rotten, hollow stumps, difficult to grub or pull. Crab-pit method consists in placing brush or kindling around the stump and covering all with clay and sods, leaving small openings for admission of air while burning. For best results, stumps should be split; done most cheaply by exploding dynamite in a ship-auger hole in the center of stump.

Blasting stumps. Tools: long-handled wood and earth auger, churn drill or pointed bar for chambering the bottom of a hole, wooden tamping bar, and blasting materials. Results of blasting depend upon: character of the roots (whether fibrous or tap), character of soil and the resistance it offers to the explosive, size and state of preservation of stump. Fresh, undecayed, fibrous-rooted stumps are harder to blast than those partly decayed or have tap roots. For tap-rooted stumps place charges against the side of the root, or in a hole bored into it. For cypress or willow stumps, or those in swampy soil, bore 3 to 6 holes, 12 to 18 in from the stump, and inclined towards it. For ordinary wood stumps, charges of 40% dynamite are given in Table 1. For green stumps, increase these charges by 1.5 to 2; for old, decayed stumps, use less than the charges given. Weaker explosive may be used for hard loam or clay, but in sand or muck 60% dynamite is better.

Table 5. Average Weights of Soils

Angle of repose. The face of a mass of earth when exposed for a ti the elements assumes a NATURAL SLOPE. The angle which a face makes the horiz when not so exposed is the ANGLE OF REPOSE (Table 6).

Angle of temporary face. Factors affecting the angle at which an eart will stand when first excavated are: kind of material, condition (wet or width of face, height of face and distance below original surface, time of exp

Clay in natural state (especially if it contains some coarse sand and gravel) will vertically for a considerable time if well drained. Saturation causes slipping. Ha holds a vertical face for a long time. Coarse sand will not stand so well as clay, but than fine sand. Saturated sand slides readily; slight dampness aids in holding it i tion. A small face, or a face under small press, will stand where a large area wi In arid regions earth will hold a steep, often vertical face, of greater height and for a time than in rainy regions. Rankine gives for greatest depths of temporary, v faces: clean, dry sand and gravel, 0 ft; moist sand, or ordinary surface mold, 3 t ordinary clay, 10 to 16 ft (13).

Table 6. Slopes and Angles of Repose

2. Methods and Cost of Loosening

Table 7. Cost of Plowing (wages $1.50, horse-keep $1, per 10-hr day)

Soil	Labor	Cu yd per hr	Labor ¢ per c
Loam.....	1 driver, 1 holder, 2 horses.....	50	1.(
Gravel and loam....	1 " 1 " 2 "	35	1.4
Fairly tough clay....	1 " 1 " 2 "	25	2.(
Very hard soil.....	1 " 1 " 4–6 " ..... 2 men on plow beam of rooter plow	15–20	5–(
Ordinary soil.....	1 driver, 6 horses, on gang plow.....	40	1.5

Barring down earth banks over 8 or 10 ft high, or undermining it picks, is an economical method. Very tough hardpan, with many boul may be barred down and picked into shape for shoveling at rate of 3 cu y man-hr, costing 5¢ per cu yd.

Loosening by explosives. Hard-... is economically loosened by ... of low-grade dynamite, Jud-... or contractor's powder. Holes, ... pt in high breasts, should be at ... to the vertical. Horiz holes in ... face of a bank are effective. For ... ils of chamber and coyote-hole ... g see Sec 5, Art 7.

Table 8. Cost of Pick-work (@ 15¢ per hr)

Soil	Cu yd per hr	Labor cost per cu yd
Loam	15	$0.010
Gravel and loam	8	0.021
Fairly tough clay	3	0.050
Hardpan	1.5	0.100

4. Methods and Cost of Shoveling

Output depends upon the material, height or distance it must be thrown, ... size of shovel. Very large shovels may be used for light soils.

... S = time filling shovel and straightening up to throw, min; t = time throwing 1 ...shful, min; d = distance carried, ft; w = time walking 1 ft with loaded shovel, min; w' = time returning 1 ft with empty shovel, min; L = load of 1 shovel, cu ft; P = percent-... of day required for rest and delays; T = time shoveling 1 cu yd after it is loosened, min.

Then
$$T = \left([S + t + (w + w')\,d]\,\frac{27}{L}\right)(1 + P),$$

reducing to
$$T = (S + t)\,\frac{27}{L}\,(1 + P) \text{ when no walking is done.}$$

Taylor gives the following values for the above factors:

	S, min	t, min			w and w'	L, cu ft			P*
		Aver	Min	Max		Aver	Min	Max	
...d or sandy loam	0.073	0.045	0.031	0.076	0.004	0.145	0.11	0.20	30
..., gravelly	0.092	0.045	0.031	0.076	0.004	0.134	0.10	0.19	30
...vel, medium	0.084	0.045	0.031	0.076	0.004	0.110	0.08	0.15	30

* This reduces to as low as 5 when much walking is done.

Table 9. Cost of Loading by Shoveling

5. Methods and Cost of Hauling

Speed of horses. A 2-horse team can travel 20 miles (10 loaded and 10 in 10 hr, over fairly hard earth roads, 15 miles over poor roads, and 25 mil good macadam, gravel, or paved streets. This gives in ft per min: poor 132 ft; fair earth roads, 176 ft; best roads, 220 ft; aver speed of 220 ft p may be expected of teams when actually walking (not including delays and

Work of horses. A good aver horse exerts a pull of about 0.1 his own when working constantly for 10 hr. For a short time he can pull about weight, at 220 ft per min (= 2.5 miles per hr). A 1500-lb horse will do 550 ft-lb work per sec, or the commercial horse-power. Two horses w pull twice as much as one, and the exact proportionate work of 2 or more as compared to that of one, is unknown; it is commonly assumed that a 2 team will pull 190% as much as 1 horse; 3 horses, 255%; 4 horses, 320%

Effect of up-grades upon size of load that can be hauled by a team definitely known, authorities differing.

Prof. E. B. McCormick found that increase of grade decreases the load that can be in each of 3 ways; (*a*) required pull per ton is increased; (*b*) possible pull of the decreased by the effort required for him to raise his own weight up the grade; (*c*) tive pull is reduced by a change in the angle of application of the pull. The first are unavoidable, but the third can be nearly, if not quite, eliminated by changing th of hitching. McCormick assumes that on grades the team's tractive effort decrease amount equal to the grade resistance due to wt of team, as calculated by the form

$$X = \frac{W}{3} - \frac{W}{100}G;$$

where W = weight of team; X = tractive effort of team; G = percentage of grad

Table 11. Loads which 1 Horse can Haul on a Grade (in terms of percent load on level, when exerting a uniform pull equal to 0.1 his weight) (Ira O. Bak

Grade	Kind of pavement						
	Iron rails	Sheet asphalt	Broken stone	Stone blocks	Best earth	Spongy earth	Mu ea
Level	100	100	100	100	100	100	1
1%	30	45	56	60	62	75	9
2%	16	27	36	40	50	57	6
3%	10	18	25	28	37	44	5
4%	7	12	17	20	27	33	4
5%	4	8	12	14	20	25	3
6%	3	6	8	10	14	18	2
7%	2	4	6	6	10	12	1
8%	1	2	4	4	6	8	1
9%	1	1	2	2	3	4	
10%	0	0	0	0	0	0	

Loads given in Table 11 are not the max loads that a team can pull. If a tea pull 2 000 lb on a very poor road for a whole day, and can exert 4 times its aver for a short time, it can easily pull the same load up a 5% grade, provided the climb is

Table 12. Tractive Resistance per Ton of 2 000 lb (E. B. McCormick)

Road surface	Tractive resistance, lb per ton	Road surface	Tractive resistance, lb per ton
[illegible] packed and dry	100	Macadam, very good	38
[illegible]sty	106	" average	46

[illegible] road, dry	61	Granite tramway	27

Table 13. Loads Hauled by 2-Horse Team (1)

Road surface	Short tons	Earth, cu yd	Road surface	Short tons	Earth, cu yd
[illegible] poor earth road	1.0	0.8	Good hard earth road	2.0	1.6
[illegible]r earth road	1.25	1.0	Good clean macadam	3.0	2.4

[illegible] distances, or over first-class pavement, much larger loads may be hauled than [illegible] Table 13.

Formula for Transportation (11): Let E = total expense per day, ct; w = net load [illegible] cu yd; s = aver speed when loaded, ft per min; ks = aver speed when empty, ft [illegible], D = length of haul in ft, measured one way; l = time lost while loading, resting, [illegible]ing, turning, and miscellaneous, per round trip, min; W = number of minutes in work[illegible]day; C = cost per lb or cu yd, ct; L = a constant representing the cost of loading, ct.

Then $\frac{D}{s}$ = time for loaded trip, min. $\frac{D}{ks}$ = time for empty trip, min.

$l+\frac{D}{s}\left(1+\frac{1}{k}\right)$ = aver time for one round trip.

$W \div \left[l+\frac{D}{s}\left(1+\frac{1}{k}\right)\right]$ = aver number of trips per day.

$Ww \div \left[l+\frac{D}{s}\left(1+\frac{1}{k}\right)\right]$ = aver total amount transported per day.

$$C = E\,\frac{\frac{D}{s}\left(1+\frac{1}{k}\right)+l}{Ww} = \text{cost of transportation, per lb or cu yd.}$$

$$C = E\,\frac{\frac{D}{s}\left(1+\frac{1}{k}\right)+l}{Ww} + L = \text{cost of picking, loading, and transporting.}$$

"Average earth" costs. The costs in following six paragraphs are for earth [illegible]erate toughness, in which a 2-horse team can plow 35 cu yd per hr (Table 7).

Wheelbarrow work. Wheelbarrows hold from 0.07 to 0.12 cu yd (175 to [illegible] lb, the aver load being about 0.1 cu yd of earth (250 lb) for work on level [illegible]runways, and about 0.07 cu yd on steep grades. One man will wheel a barrow [illegible] 15 miles per day. While dumping, about 0.25 min per trip is lost, or [illegible] min per cu yd, when barrows hold ⅛ cu yd. About the same time is [illegible] while changing barrows and in delays. With wages at 15¢ per man-hr, [illegible]st of picking, loading, and lost time is 17¢ per cu yd. Cost of hauling is [illegible]¢ per cu yd per 100-ft haul for level runways, and 5¢ per cu yd per 100-ft [illegible] on steep grades.

Cost of wheelbarrow work (wages, 15¢ per hr): To a fixed cost of cu yd add 5¢ per cu yd per 100-ft haul, on steep grades, and 3.5¢ on le ways (1).

Cart work. One-horse, two-wheeled, dump carts hold 0.3 to 0.5 On ordinary road loads of earth seldom exceed 0.4 cu yd (place measu loads of 0.48 cu yd gravel and 0.52 cu yd sand are common, and 0.59 cu 0.63 cu yd may be carried. Double carts and wagons hold twice as m single, the loads being limited by condition of the road.

With hauls of 300 ft or less, 1 driver can attend 2 carts by taking one to the dun the other is being loaded; on long hauls, and where the relative positions of pit an are fairly constant, horses may be trained to travel without a driver.

Cost of cart work. A cart can be loaded with 0.4 cu yd in 3 min by of 4 or 5 men, and should be dumped in 1 min. If cost of a horse and $1 per 10-hr day, and the driver's wages $1.50, then the cost of a cart a a driver is $1.75 per day; hence, cost of lost time is 3¢ per cu yd. Co dumpman is 1¢ per cu yd, if 150 cu yd are delivered to him in 10 hr. (picking and loading is about 15¢ per cu yd. To determine total cost, ad per cu yd per 100-ft haul to the fixed cost of 19¢ per cu yd, as above. Fo easily plowed and shoveled, the fixed cost may reduce to 14¢ per cu yd. a driver for each cart, the cost of hauling is 1¢ per cu yd per 100-ft ha carts carry 0.67 cu yd the cost of hauling is 0.5 ct per cu yd (1).

Wagon work. There are 3 types of 4-wheeled wagons in common us tom-dump; end or rear-dump or double cart; and slat-bottom. The las is not now often used, and the end-dump wagon is employed chiefly wh is dumped from piers into scows. Double carts and wagons hold about as much as single, their loads being limited by the condition of the road 13). Two-horse teams are the rule, but 3 to 6 horses are often very econo as almost 50% greater load can be hauled by 3 horses and a proportio greater load by a greater number.

Cost of wagon transport depends upon time lost in loading and dur and upon speed of the horses. Loading time should not exceed 4 or Having extra wagons to be loaded while the teams are traveling to and the dump materially reduces lost time. A team can be changed fro wagon to another in 1 to 1.5 min. Dumping time: 0 to 0.5 min for bo dump, 1 min for end-dump, and 1.5 to 3 min for slat-bottom wagon (1). suming cost of loading earth at 13¢ per cu yd, and cost of lost time for a and driver at 5¢ per cu yd (with wages of team and driver at 35¢ per h fixed cost of wagon transport is 18¢ per cu yd.

At speed of 2.5 miles per hr, the cost of wagon work per cu yd is found by addi following rates per 100-ft haul per cu yd to a fixed cost of 18¢: For 0.8 cu yd loa 0.66¢; 1.0 cu yd, 0.53¢; 1.6 cu yd, 0.33¢; 2.0 cu yd, 0.26¢; 2.4 cu yd, 0.22¢.

Cost for traction engines and large wagons. For 3-yd wagons hau trains (11), use the following factors in the transportation formulas given a

E = total expense per day, = 2 100 cents, made up as follows: Engineman, $3; fir $2; coal for 10 miles (1.25 ton @ $2.25), $2.82; repairs (traction engine and 12 wa $4.30; deprec (traction engine and 12 wagons), $3.53; int (traction engine and 12 wa $1.72; misc and superintendence, $3.63; total, $21.

w = 25 tons, plus or minus (3 to 8 wagons of 3 cu yd or 4 to 5 tons each).

s = 242 ft; $\frac{s}{t}$ = 266 ft per min.

t = 30 min (including getting coal and water). W = 600 min.

L depends on method of loading.

(Interest is based on working season of 7 months, of 25 working days, or 175 wo days per year.)

...st with automobile truck (11).

... = wt of live load, ton; m = dead load of vehicle, ton; s = speed loaded, ft per ... = speed empty, ft per min; D = distance of haul, ft (one way); l = lost time per ..., F = fixed charges per working day, as: int, insurance, taxes, deprec, storage. ...portion of fixed annual charges should be based on number of actual working ...r year, with due allowance for bad weather, break downs, etc); O = operating ...es per working day, cents, as: fuel, waste, oil, chauffeur and other labor, repairs; ...mber of minutes in working day; R = transportation cost per ton, cents; N = ... round trips per day of W min.

... = time for loaded trip, min. $D + ks$ = time for empty trip, min.

$l + (D + ks)$ = actual non-productive time per trip, min.

$\frac{1}{s}\left(1 + \frac{1}{k}\right)$ = total time per trip, min.

$W \div \left[l + \frac{D}{s}\left(1 + \frac{1}{k}\right)\right]$ = number of trips per day.

$Ww \div l - \left[\frac{D}{s}\left(1 + \frac{1}{k}\right)\right]$ = aver amount transported per day.

$O + F \div \left[l + \frac{D}{s}\left(1 + \frac{1}{k}\right)\right] \div Ww = R$ = cost of transport per ton for distance D.

$w \div (m + w)$ = carrying efficiency of vehicle, percentage.

...ctors and bottom-dump wagons. Trailer wagons drawn by auto- ... trucks or tractors are economical for long hauls. An auto truck can ... its rated load, and under proper conditions haul in trailers excess loads ... to 300%. Tractors are usually 3 or 4-wheeled automobiles, with a ... fifth wheel and king bolt for hauling a 2-wheeled trailer. Trailers are ... dump type, of 3-ton (76 cu ft) and 5-ton (120 cu ft) capacities. They ... time lost by the tractor when loading and dumping; front of the trailer ... jacked up and its body loaded while the tractor is hauling another ...

... vantages of tractor and trailer over ordinary type of auto-truck are: simplicity of ... and consequent reduction in first and maintenance costs; reduction in tire ... maintenance, due to use of springs; lessened shocks in starting and stopping; ... of parts. Disadvantages: difficulty of turning in small space; can not back ... distance, tractive power is insufficient on very bad roads.

...ars. There are 6 methods of moving cars in excavation work: by hand; ... or mule; by locomotive; by cable; by self-contained motor and electric ... by gravity, combined with one of the other methods.

... of 6 classes: small ½ to 2-yd light, steel, narrow-gage, side or end-dump cars, ... moved by hand or horse; small 3 to 8-yd wooden, narrow-gage, side-dump cars, ... pulled by contractor's locomotive; standard gage, wooden or steel-side dump ... to 12-yd capacity, generally pulled by large contractor's locomotive; standard- ... cars and standard locomotives; small, narrow-gage side or end-dump cars, ... mules, cable or small air-electric industrial locomotives; special quarry or in- ... cars, equipped with motors.

...ransportation by small cars. Double side-dump, V-shaped, steel cars, ... to 54 cu ft, weigh 700 to 1 800 lb, and cost $50 to $100 each. When the ... excavated lies higher than the dump, these cars traveling under grav- ... pulled back by horses or cable are economical.

... ...ation of a 14-ft bank of hardpan was completed in 1907 with an outfit of this ... Plant: 12 36-cu ft cars, 600 ft of 36-in gage track with turnout and switches, ... $1 345. Labor cost per day: 1 foreman, $3; 6 pick and bar men, @ $1.50, $9; ... men, @ $1.50, $18; 1 horse and driver, $3.50; 2 dump and track men, @ $1.50, ... mouth (proportion), $1.75; Total, $38.25. The soil was undermined by picks

and bars, loaded into 6-car trains, and run by gravity down a 4% grade to the The empty cars were pulled by 1 horse. 198 cars (about the same number of cu y measure) were dumped in 10 hr, giving a labor cost of 19.3¢ per cu yd.

Cars and locomotives. Dump cars or standard railway cars are ge used for steam-shovel work. Common sizes, for contractor's locomoti "dinkeys," are 4, 6, or 8-yd; track gage, usually 3 ft. Track is common with 30 to 50-lb rail, few ties, and unballasted. ROLLING RESISTANCE on such roughly laid rails is far greater than on straight, well-ballasted R R while commonly assumed as 15 to 40 lb per ton, it is seldom less than 40 often 50 lb or more. STARTING RESISTANCE of dirt cars on rough track is ably double the rolling resistance.

R. V. Norris (*Trans* Am Inst Min Engs, Vol 18, p 508) gives result of several h traction tests on mine cars. To start empty and loaded cars required a pull of 8 lb per ton; to keep them moving, 26 to 66 lb per ton. A. W. Wright, from tests on drawn street cars in Chicago, foun the pull to start cars on dirty rails av 134.5 lb per ton, and 32.3 lb to keep t motion. C. E. Emory, from experim N Y, found a resistance of 11.8 lb. Tl probably on clean center-bearing rail, P. Holt found 15 to 46 lb per ton on straight track. H. Hughes found 26 lb, and M. Treaca, 22.4 lb.

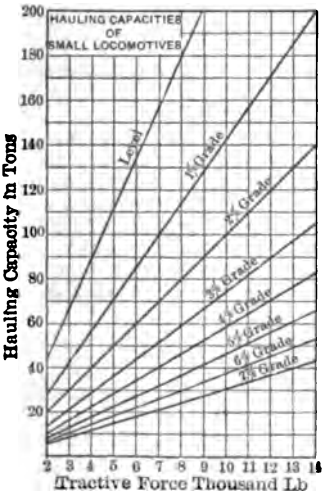

Fig 1. Hauling Capacity of Locomotive on Grades

Rule for calculating hauling c ity (H. K. Porter). Divide tractive of locomotive by resistance per ton gravity and rolling friction; then d wt of locomotive (and tender, if This gives the wt in tons (includi of cars) that the locomotive can Tractive force of a locomotive: $(T = + D$, where T = tractive force, lb; d = of one piston, in; L = length of strok P = press of steam in cylinders, lb D = diam of driving wheels, in

Hauling capacity of construction lo tives is given in Fig 1. Rolling fricti assumed at 40 lb per ton; resistance d gravity is approx 20 lb per ton for eac cent of grade.

Struck- or water-measure capacities and weights of dump cars are g in Table 14. Actual capacities, earth measured "in place," is 75 to 80 the water-measure capacity. See also Table 3, p 119.

Table 14. Dump Cars, Capacities and Prices

Water measure, cu yd...	0.67*	1.0*	1.5*	2.0*	4†	6†	8†	1

Price, $.....	54	58	70	100	180	300	450	

* Steel: V-shaped, double-side dump cars. † Wood: diamond-frame, double-side dump

Speed of "dinkey" locomotives is from 5 miles per hr when hauling lo to 9 miles per hr empty or on a down grade. Grades should never exceed **if avoidable.**

... of hauling cars depends mainly upon output of the steam shovel loading ... On hauls up to 1 000 ft 1 dinkey can often serve a 1.5-yd shovel. About ... min is required for 1 man to dump and clear a 3-yd car. Under favor- ... conditions, 1.5 to 2 min are lost in switching a train.

... of contractor's track depends upon the prices of rails, ties, and fastenings, and the ... and efficiency of the men employed. Weight of rail for contracting work is usually ... per yd, although 16 and 20-lb rail is common in mines and quarries where ... semi-permanent. For 3-ft gage track, a 6 by 6-in by 5-ft tie is best. About 375 ft ... these ties, and 1 ton of 30-lb rail, are required per 100 ft. Cost of laying construc- ... after grading road bed and delivering the material, is from $2 to $6 per 100 ft.

... of daily operation of 2 dinkeys, assuming 132 working days per year (2):

... men (on 2 dinkeys) @ $3; 2 trainmen @ $2; 6 dumpmen @ $1.75	$20.50
... for 2 dinkeys, 0.6 ton @ $4	2.40
... at $1.50; oil and waste, $0.50	2.00
... on $6 000 (2 dinkeys, 24 cars), @ 6% per year + 132 days	3.65
... on $6 000, @ 1.5% per month + 22 days	5.45
... on $8 000 @ 8% per year + 132 days	4.85
... & housing locomotives & cars once during year, say $500 + 132 days	4.00
Total charges: train crew, fuel, repairs, care of locomotives and cars	$42.85
... grading and track shifting @ $1.75	$10.50
... on $2 250 (35-lb rails for 1 mile of track), @ 6% + 132 days	1.00
... on $2 250, @ 12% + 132 days	2.00
... on $750 (ties, at 30¢, 2 miles track), @ 6% + 132 days	0.35
... on $750 (ties), @ 10% per month + 22 days	3.50
Total track crew and track	$17.35

Hauling engine and cable are often used to pull cars on grades when the ... not over 1 000 ft or less. Cars will coast down a grade of about 3%, and may ... hauled back by cable (Sec 11).

6. Scraper Work

Drag or slip scraper is an open-front steel box, or scoop, usually provided with run- ... a false sheet of steel, to take wear. Wooden handles at the rear are for loading and ... it. The bail, for the whiffle-trees, is pivoted at the sides near the front. Two ... are usually used. Common sizes of drag scrapers, No 1, 2, 3, are listed as holding ... 1 cu ft respectively. Actual capacity (place measure) is about 0.5 list capacity. ... $4; to $5; wt, 75 to 90 lb each.

Cost of work. Drag scrapers are economical only for short hauls, or where ... excavation is in confined places. The minimum "run-around" or total ... for any kind of scraper work is about 150 ft. LEAD is the aver straight ... between center of cut and center of fill; it is shorter than the actual ... by the distance required for turning and handling the team. About 0.33 ... min per cu yd is lost while loading and dumping. With wages of team ... driver at 35¢ per hr, cost of loading and dumping is about 2.75¢ per cu yd, ... turning 1.5¢, and for lost time, turning, etc, 2¢, making total fixed cost in ... of 6.25¢ per cu yd. To this add 4.5¢ per cu yd per 100 ft of lead for a ... scraper. Cost of foreman's wages adds about 0.75¢, and wear and tear ... scrapers about 0.25¢ per cu yd. Work in stiff clay may cost 30% more (1).

Buck and Fresno scrapers. Simplest form of buck scraper is an upright board, 8 ft ... with a tongue for the team and a rear platform for the driver. From this the ... graders and levelers have been developed. Fresno scraper is a long pan, open ... top, and without a pole. It is handled like a drag scraper, except that 4 horses ... instead of 2 are used. Common sizes are No 1, 2, 3, having a listed capacity of ... and 12 cu ft, and an actual aver capacity of 9 54, 7.42, and 6.36 cu ft, respectively. ... $5 to $6; wt, 250 to 300 lb.

Cost of work of 4-horse Fresno scraper, holding 0.5 cu yd, with
driver and horses at $6 per day, is found as follows: To a fixed cost
cu yd, add 1.75¢ per 100 ft of lead. Fixed cost includes extra distance
while loading and dumping, shifting of the gang, and 1¢ for plowing.
is 9 cu ft, the fixed cost is 5¢ per cu yd and the traveling charge per 10
is 2.67¢ per cu yd. To this add 0.5 to 1¢ per cu yd for foreman's wages.
scrapers are usually more economical than Fresnos for hauls exceeding

Wheel scraper is a steel pan hung hinged between 2 wheels, with a pole for
and a lever in the rear for lowering the pan when loading and for upsetting it wh
ing. Sizes are No 1, 2, 2½, and 3, with listed capacities of 9, 12, 14, and 16 c
actual aver capacities of 8, 8.75, 12 and 15.5 cu ft, respectively. Costs, $2
wt, 330 to 750 lb.

Cost of work with wheel scrapers is found by adding a traveling
100 ft of lead to a fixed cost per cu yd. Costs in Table 15 are based o
@ 15¢ per hr for men, or 35¢ for team and driver (2).

Table 15. Costs of Wheel-scraper Work

Number or size of scraper	1	2
Load hauled, cu yd	0.2	0.25
Loading and dumping cost, ¢ per cu yd	1.5	1.2
Man for loading, ¢ per cu yd	0.8	0.8
Plowing, " " " "	1.5	1.5
Extra team travel, " " " "	1.5	1.2
Snatch team, " " " "	.....	1.5
Man for dumping " " " "	.....	.....
Total fixed cost, ¢ per cu yd	5.3	6.2
Traveling cost per 100 ft lead, ¢ per cu yd	2.75	2.2

Cost of foreman and repairs adds about 1¢ per cu yd.

Maney 4-wheeled scrapers, hauled by 2 or 4 horses or a traction engine, ar
tially self-loading 4-wheel wagons. Loading and dumping are controlled by s
and chains from the rear wheels. Capacity is 31 cu ft struck measure, but th
measure capacity is little more than 50% of this. Cost of field labor and team is
per cu yd, for 250 ft lead.

Levelers and graders. TONGUE SCRAPER is a wooden platform drawn at an
60° with the surface of the ground by 2 horses. It is economical for spreading
earth, and filling shallow ditches; cost, about $7. ROAD SCRAPERS and DRAGS, for
ing ruts in roads, cost $12 to $20. Standard ROAD MACHINES weigh 1 500 to 2
cost, $125 to $260. They are drawn by 2 or more (generally 4 or 6) horses or by
tion engine, and are used for spreading earth on embankments, grading roads, a
ging shallow ditches. Small, 2-horse, 1-man road machines, of several types, we
to 900 lb and cost $50 to $150. They are economical for light grading and spre

Elevating graders for loading wagons. Best conditions: ample room for turni
maneuvering the teams, and ground fairly level, with few boulders or roots. The m
is a 4-wheeled truck, carrying a heavy plow which turns its furrows upon a lateral, u
sloping belt conveyor, whence the material is discharged into wagons or falls
ground. It is propelled by a traction engine, or 10 to 12 horses (8 in front and 4 b
The conveyor is driven by gearing, or a gasoline or steam engine. Cost, $1 000 to
weight, 5 to 9 tons. Capacity under favorable conditions, 400 to 1 000 cu yd in

Cost of grader work, at an output of 500 cu yd per 10 hr, is as follows
wages at $1.50 for driver, and $1 for a horse, the fixed cost of 10 horse
4 men on the grader is 3.5¢ per cu yd; of 5 men spreading on the dump,
and of int, repairs, and deprec, $5 per day, or 1¢ per cu yd. To these is add
cost of the waste labor of the teams following the grader to receive their lo

...ges of a driver and 3 horses on a dump wagon holding 1.25 cu yd are $4.50 per ...day. the cost of hauling is 0.6¢ per cu yd per 100 ft of lead, or 2.5¢ per cu yd for the ... 100 ft of waste lead traveled by the wagons. Hence, to find the cost for a given ... 0.6¢ per cu yd per 100-ft lead to a fixed cost of 8.5¢. With a traction engine ...ixed cost is reduced by 0.8¢ per yd. If water for the engine must be pumped and ...cost may be increased 0.5¢ or more per yd.

...son or power scrapers vary in shape from a horse-drawn drag scraper to a bot... box-like affair.

Bottomless power scraper (Fig 2) holds from 0.5 to 7 cu yd and costs $250 to $600. ...able cutter edge is fastened on a runner frame adjustably connected to the back-... This machine is especially economical in sticky material, as the load is not dumped

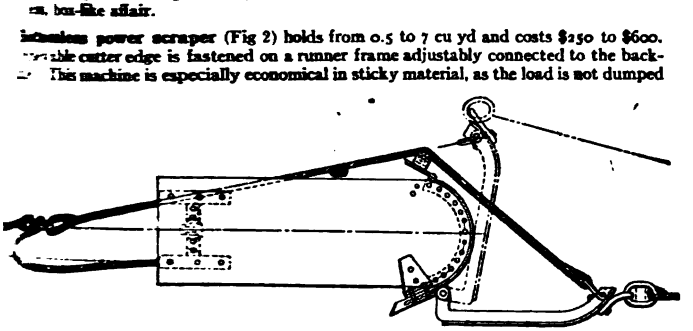

Fig 2. Bagley Grader (Bottomless)

... load rests on the ground and is dragged to the point of deposition. It requires a ...-hp engine, ⅞ to 1-in haul-back line and 1 to 1.25-in pulling line. Approx oper... cost is $28 per day. With a 600-ft haul, about 15 trips per hr should be made; ... 300-ft haul, about 6 trips. An output of 500 cu yd per 9-hr day can be averaged ...favorable conditions.

Drag-line scraper excavators (Fig 3) are operated by locomotive cranes, field ...rs or derricks, with cables, or by dredges. Fig 4 shows a drag-line excavator

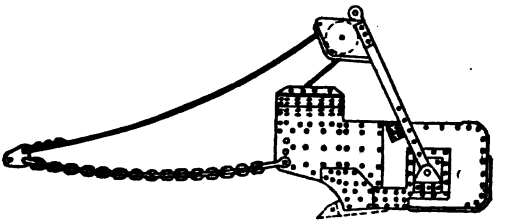

Fig 3. Page Drag-line Scraper

... boom derrick type. Scraper buckets are of various shapes, so arranged ...lt forward or backward in dumping. They hold ¾ to 5 cu yd, and cost ... $500 per cu yd of capacity, not including rigging nor power plant.

...st of operation of drag-line excavators varies with type of bucket, operating ...ng, kind of earth, and local conditions. Sauerman excavator, wherein the ...is drawn in one direction by a pulling line, and allowed to slide back by gravity ...ad cableway (Art 7), will, under favorable conditions, excavate and deliver earth ...ost of 300 ft for 5.5 to 10¢ per cu yd. A scraper excavator machine of the full ...ng or "whirly" type, has an upper platform rotating on a lower frame. The ...gine and long boom for operating the scraper are carried on the platform. These ...ines cost from $5 000 to $10 000 complete. Cost of operating in well compacted ... and gravely soil is 5 to 7¢ per cu yd (12).

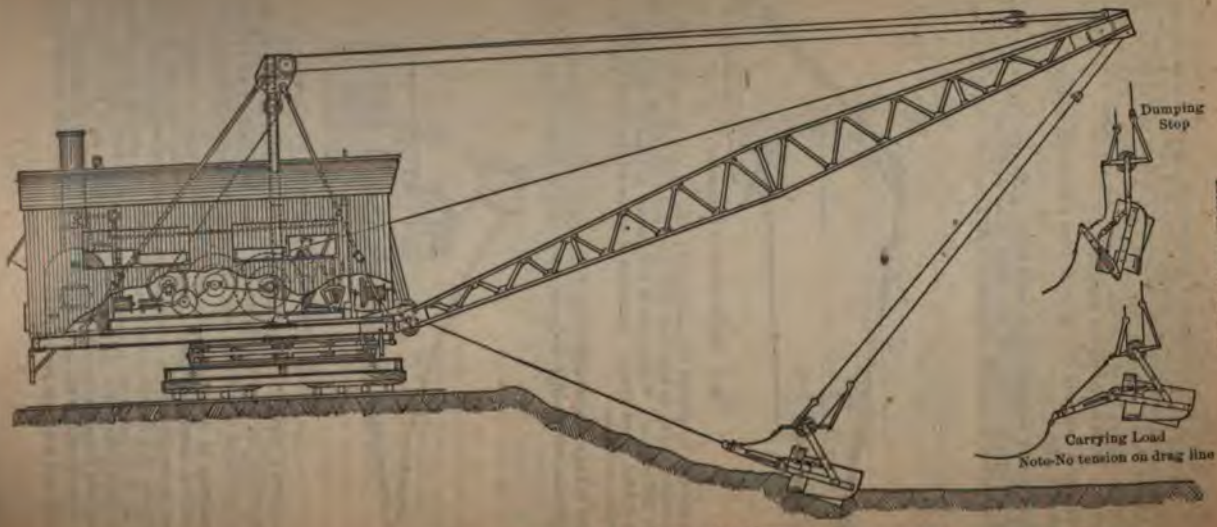

Fig 4. Boom-derrick Type of Drag-line Scraper

7. Cableways and Belt Conveyors

ays. For design and construction, see Sec 26. When the track cable is
d that the sag may be varied, at will of the operator, thereby directly
raising the load, the machine is a SLACK CABLEWAY. For operating a
avator bucket, one end of cableway is set higher than the other, and
oaded or empty bucket moves by gravity. When loads are all carried
ction it often pays to have the dump end lower than loading end.

e use of cableways requires: (*a*) work on a scale large enough to warrant
rst installation, plus costs of ensuing removals and reinstallations; (*b*) enough
the length of span, and within economic reaching distance each side of the
o repay cost of one installation and removal. These conditions are often
h and canal excavation and dam construction.

pends on length of span, height and type of towers, and amount and
er required. In general, cableways for operating, digging, or convey-
cost, installed complete, from $8 to $15 per ft of span, for spans of 400
d from $6 to $12 per ft for spans of 1 000 to 2 000 ft. Duplex cable-
2 complete cables 15 to 20 ft apart on common towers) cost about $12
pans of 2 000 ft, with towers 75 to 130 ft high (see also Sec 26).

operation (see Sec 5, Art 8, 11; Sec 26; and Bibliog 1, 2, 7, 8, 9, 11).

nveyors. For design and construction, see Sec 27. In earth exca-
nveyors find their most important employment as accessories to
hines, as dredges, trench excavators, and elevating graders. But
metimes used in long lengths for excavating cellars, and transport-
l from boats (1, 2, 7, 8, 9, 11).

. A cellar excavation for a power house was made in New York (1899) by
r. A trench 7 ft deep was first excavated; across it were erected 3 bridges
above the conveyor, and the earth was moved to the hatches by wheel
With a 30-in belt the daily output exceeded 1 200 cu yd (7). In 1908 a flat
r 2 100 ft long was built in the South for conveying shale from a quarry to a
. The belt was 24-in, 8-ply, in 2 sections, one being 1 000 ft between centers,

Guide rollers were placed 40 ft apart. Contraction and expansion were
tension carriages. Since all loads were carried down grade, more power was
operate the belt empty than when loaded. Power was furnished by two
es. Cost of installation was $9 106, or $4.37 per lin ft. Cost of operation
nance (including labor, power, supplies, int, deprec, and renewals, estimated
cost) was $4.04 per 10-hr day, or 2¢ per ton. Cost per unit of operation is
a capacity of 200 tons per 10 hr (E. C. Soper, Am Soc Mech Engs).

8. Steam-shovel Work

ovels. USUAL DESIGN. The dipper and its arm or handle move in a verti-
pported by a derrick and boom, rotating horizontally. By a rack and pinion,
rice, the dipper arm runs in and out with respect to the boom, so that a load
and dumped at any point within the reach of the machine. SPECIAL DESIGNS.
rican milway ditcher, the dipper arm is hinged to the boom, the cutting
adjusted for each case. In the Thew shovel, the length of dipper arm is
required by bolts, and its inner end is attached to a carriage traveling back
orizontally on the boom. In a broad sense, the term steam shovel includes
land dredges, operating clam-shell and orange-peel buckets.

vels usually run on standard-gage track; lighter machines on narrow-gage
ounted on a truck with broad-tire wheels for road traction. For excavat-
they may be mounted on rollers on a platform spanning the trench. Land
ally run on rollers or on very broad-gage wheels, or, in marshy ground, on
wheels." Ditchers, for R R work, usually travel on track laid on the
flat cars being loaded. (1, 2, 4, 5, 7, 8, 9, 10.)

9. Dredging

Types of dredges: dipper; grapple or grab-bucket; ladder or bucket-elevat
draulic or suction. Those having bunkers or hoppers for carrying the dredged m
are "hopper dredges" (1, 2, 6, 8, 9, 11).

Dipper dredge is essentially a steam shovel mounted on a scow. There are 3 clas
drainage and irrigation ditches; for deep water and harbor improvements; and fo
work. Ditching dredges are small, with narrow hulls and telescopic bank spuds
dredges have narrow hulls and side floats; deep-water dredges, for depths to 50
generally of large size, with spuds operated by independent engines. Wooden h
common, but steel hulls are now favored.

Grapple dredge is a floating derrick, with clam-shell, orange-peel, or other
grab bucket. It serves for very deep water or in confined places.

Ladder dredge, popular abroad, is especially adapted to gold placer mining
construction and use, see Sec 10.)

Hydraulic dredge is a scow, carrying a centrifugal pump, with a suction pipe r
to the bottom to be excavated, and a discharge pipe to place of deposit. In all exc
easiest materials, a revolving cutter at the mouth of the suction pipe is requi
loosening the soil. Special advantage of this dredge is its ability to convey ex
material long distances.

10. Hydraulic Excavation

This method originated in California for excavating gold-bearing gravel. I
DRAULIC MINING, pipe, monitors, ground sluices, etc, see Sec 10. Hydraulic m
are here considered for moving material in ordinary excavation, as for hydra
dams, railway embankments, and ordinary grading (1, 3, 11).

Hydraulic-fill dams. With enough water, a sufficiently high working fa
grade to convey the mixed earth and water, dams can be built more cheaply
well) by hydraulicking than by ordinary methods of embankment with rolli
tamping. Water is delivered by pump or gravity to a HYDRAULIC GIANT or
TOR; pressure at nozzle, 100 to 150 lb per sq in; velocity, 100 to 200 ft per se
ume, 10 to 15 cu ft per sec. When water is scarce the waste may be led to a si
clarifying basin, and used again. The soil, after being loosened by the mon
carried by sluices to pipes or flumes and thence to the dam. The bank from
the earth is washed must be at a higher elevation than crest of the dam, grad
dam being at least 2% for fine materials, and 6 to 8% for coarse, heavy stu

The solid material hydraulicked may be retained by the SUMMIT POOL or SHEA
method. The first is the commoner, consisting in keeping the sides of emba
higher than the center by discharging the mixed water and solids along the sides.
water runs off through drains, the entrances of which are kept above the center
finished part of the fill, thus forming a summit pool or settlement basin. This
only successful method for clay or other slow-draining soil. In the shearboard
the water and its contained solids run lengthwise of the bank, the stream being
from place to place. The slopes are formed by "shearboards," consisting of p
laid edgewise and held in place by vertical stakes. The embankment is built fr
ends instead of from the bottom up, as with the summit-pool. This method
applicable in grading sand and gravel, or other fast draining soils, where terraces
steeper slopes than the natural surface are desired.

The pipes and flumes discharge directly at the sides of the dam, or th
laterals that can be shut off at any time. When any one material begins t
a pervious layer through which water can percolate, the soil must be kn
and mixed by men working with long boards or poles from a raft. Perc
of solids carried by the water in dam construction averages 20 to 25%, r
from 5% to 50%; it depends on hardness and other characteristics of th
quantity of water, and grade of flumes (16).

Cost of the Concully dam (15). This dam is part of the Okanogan project
U S Reclamation Service, at Salmon Creek, Washington. It was made of a talus

formed from disintegration of granite, mixed with angular rock fragments. Water ...med by a diversion from West Fork of the creek, through a 3-mile flume. Creek flow ...50 ft per sec and more during April, May, and June, to 10 ft per sec in Aug and ...ater supply flume, dirt flume, spill-way, etc, were built in 1907. In 1908, 97 000 cu ...aced, in 1909, 188 000 cu yd; and in 1910 the remaining 64 000 cu yd. In 3 years ...percentage of material carried by the water was 2.85, 2.42, and 1.87 respectively. ...was $324 325, or a cost per acre-ft of $24.95 for 13 000 acre-ft. The hydraulick- ...$155 637, or 45.79¢ per cu yd, place measure; unusually high for such work. Table ...itemized costs. Wages per 8-hr shift: Common labor, $2.25 to $2.50; pitmen, $, giantmen, $3; powdermen, $3; carpenters, $4 to $4.50; foreman, $5.

...ern Pacific R R embankment. In 1896–7, a number of trestles were filled ...t by the hydraulic method. In 8 cases, where there was a gravity supply ...the cost was 4.79¢ per cu yd. In one case, pumping was necessary, making a ...¢, which included clearing of dense forest growth (Table 21). Plant includ

a No 2 giant, costing $95, and 300 to 1 000 ft of light sheet-iron pipe, at 27 Sluice boxes were paved with 3-in blocks, and when removing gravel or rock on grades of 7 or 8% (1).

11. Trenching

Methods: By hand; with scrapers, drawn by horses or cables; with gral loaded buckets on a cableway or overhead track; by trench excavators, stea land dredges, or derricks.

Hand work. Cost depends on hardness or tenacity of the soil, n boulders or other obstructions, presence of water, and depth and (sc on the width of trench. In trenches over 4 ft deep, some of the soil shoveled twice: first, to the surface; then, as the spoil pile grows, b edge of trench. In trenches 6 to 12 ft deep, the soil must first be thr staging about halfway up, thence to the surface, and finally, back-from For depths of 12 to 18 ft, the soil must be handled 4 times.

From studies by the Construction Service Co (4) of sewer, drain, and water-pip tion, in aver soils, 9.23 cu yd per man per 10 hr are excavated in trenches 3 to 7.37 cu yd for depths of 6 to 12 ft, and 6.38 cu yd for 12 to 18 ft. (For dee trenches, machine excavation is better than hand work.) These rates are as hi be expected for aver trenching; when water, quicksand, or boulders are present the men and superintendence are less efficient, costs may reach $1.25 per cu yd of trench affects the cost. In narrow work, men are cramped and can not work e in very wide trenches, cost of removing the spoil from the edges increases tota

Cost of back-filling depends on: nature and condition of soil (whether fro packed, or dry); means employed to back-fill; amount of tamping require back-filling and tamping are done by hand, work per man-hr ranges from 1- aver 1.5 cu yd; most compact tamping (clay excepted) is obtained by casting water; for thorough dry tamping on large-scale work, power tampers should

Stayley power-tamper will strike in a trench from 1 to 4.5 ft wide by 6 ft weighs 950 lb, costs $300, and requires 1 operator and 1.5 gal gasoline per 10 hr. 60 blows per min and, assuming 50% lost time, should cover 900 sq ft per hr; or, in 3 ft wide and 5 ft deep, tamped in 6-in layers, should compact 30 lin ft of trenc

Labor cost of sheeting in small trenches is from 0 to say 25¢ per trench, or 0 to 1.5¢ per sq ft of wall; aver, about 0.4¢.

Trench excavation by scrapers is advantageous in trenches wide for a team, and in soil free from obstructions and not requiring sheeting. cableways, with scraper-excavator buckets, are economical on wid trenches, and may be used even where braces and sheeting are necessar

In building a 7-ft sewer in sand at Gary, Ind (2), where the ground-water at ma was level with the surface, the trench was unwatered to depths of 6 or 8 ft, and Schnable drag scraper was used to dig to water level. This held 2 cu yd and oper 58-ft boom. Excavation amounted to 10 cu yd per lin ft of trench, and the mac 60 lin ft per day. (This was not its full capacity, but the speed was determine rest of the work.) The machine was mounted on rollers traveling on a timber t by dumping some of the soil ahead of itself, formed its own roadbed. The moved itself, using the bucket as an anchor for the drag line to pull on. Aver 400 cu yd in 9 hr, with 1 engineer, 1 foreman, and 4 laborers. Costs were as f

	Per day	Per lin ft
Scraper excavator work (400 cu yd)	$22.25	$0.370
Shovel excavation (300 cu yd)	170.00	2.833
Sheeting and bracing (300 cu yd)	29 50	0.491
Pumping and pipe system (300 cu yd)	94 50	1 575
Back-filling (500 cu yd)	20.25	0.337
Miscellaneous (300 cu yd)	7 00	0.116

Outfit, ... about 19 tons, can be loaded on 1 R R car. Price of a 300-ft cableway ... is about $3 250; 400-ft cableway, about $3 500; they can be hired ... $200 to $225 per month. Engines are usually 7 by 10-in duplex, mov... buckets at about 440 ft per min. To move the machine to a new posi... road, requires from 4 hr to say 3 days, depending upon method used and ... of the men (1, 2, 7, 8).

... 1 trench 14 ft wide by 18 ft deep, in earth slightly more compact than average, ... 400-ft Lambert cableway, delivering buckets through a chute into R R cars, was (1):

	Per day
... loading buckets, @ $1.50	$45.00
...signalman (signaling to engineman) @ $1.75	1.75
... hooking on baskets, @ $1.75; 1 man dumping baskets @ $1.75	3.50
... driving sheet plank and bracing, @ $1.50	6.00
... spreading earth in cars and moving cars, @ $1.50	7.50
...engineman $3; 1 fireman $1.75; 1 water boy $1; 1 foreman $4	9.75
Total	$73.50

... in above work was 260 buckets in 10 hr, each holding 1.3 cu yd loose earth, or ... more than 1 cu yd in place. Wages and coal, $76 a day. Hence, not including ...ering, nor hauling and unloading of cars, the cost of excavation was about 30¢ ... There was no back-filling, as the trench was for a retaining wall.

...ench machines are usually earth conveyors rather than excavators, ...h grab buckets operated by a cableway are included. In general, they ... a cableway or an over-head track, carried longitudinally directly ... the trench. The Adams trench machine comprises a series of wrought-... bents, supported on wheels. Under the top of the bents is a ... the bucket carriage. In the Moore conveyor, the rail for the bucket ... is supported by A-bents. Potter machine has a track on top of the ... which travels a car carrying a hoisting drum. Two men stand on the ...erate the buckets. Carson machine comprises a rail supported on rec... A-frames, with a rail for a train of 6 connected carriages and buckets, ...ing 0.2 cu yd. Its working length is about 288 ft; total length, 336 ft. ...ds on a T-rail track, and may be pulled ahead to a new position by its ...gine. Cost, about $3 400; capacity, about 250 cu yd in 19 hr.

...rking force for a Carson machine, in a 4 000-ft section of the Metropolitan sewer ... boston, comprised: 1 engineman, $3; 1 lockman, $2; 1 dumper, $1.50; 8 shovelers, ... $14; 2 bracers @ $2.50, $5; 2 tenders @ $2, $4; 4 plank drivers @ $2, $8; 2 men ...ing planks @ $2, $4; 8 men pulling planks, etc, @ $1.75, $14; total, $55.50. ...trench was 9 ft wide by 20 to 30 ft deep; aver advance per week, 64 lineal ft in ...y sand, 192 ft in gravel and coarse sand, at a cost of from 25¢ to 80¢ per cu yd. A ... compounding $20 per day was required. Fuel consumption, 0.5 ton coal per day (1).

...raveling trench excavators comprise: the wheel type, in which exca... buckets are carried on the perimeter of a wheel; ladder type, in which ...ng buckets or scrapers are carried on a belt traveling on a ladder frame. ... power plant and excavating mechanism are mounted on tracks, platform ..."crawler" wheels. The earth is scraped into the buckets and carried to ... above the ground surface where it is dumped on a belt conveyor and ... to one side of the machine. These machines do not work efficiently ... containing boulders or other obstructions.

Buckeye machine is of the wheel type. It weighs 5.5 to 51 tons, costs $200 to
ton, and excavates to depths of 4.5 to 12 ft. At Greeley, Colo, a 36-mile wa
trench (excepting 2 000 ft in rock) was dug by a 17-ton machine, 8 miles being in
gravel, the rest in clay. A trench, 30 in wide by 4 ft deep, was dug at an ave
627 ft in 10 hr, at a cost of 14¢ per lin ft. Machines of the belt type are: the M
Parsons (Fig 5), Austin, and the Insley. In laying 7.5 miles of pipe sewers at Ma

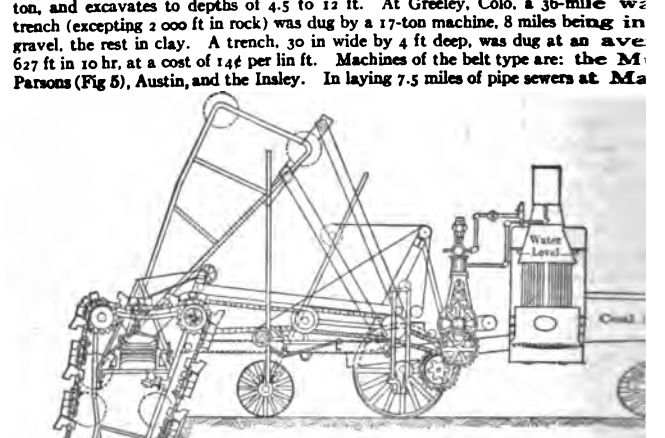

Fig 5. Parsons Trench Excavator

Wis, the daily cost of operating a Municipal machine and lab
was $35. The trench was 27 in wide by 7 ft aver depth, an
500 lin ft, or 300 cu yd, were excavated per day.

Steam shovels for trench excavation are suppo
timbers spanning the trench. As their weight comes
on the banks, they can not be used in soft ground
the walls are well sheeted and braced. The shove
usually be stopped while the trench is being sheeted,
consequent delays materially decrease the output.
excavators, though not subject to this delay, can not
so difficult soil as steam shovels.

From observations by the Construction Service Co, the fo
data are compiled (4). A 25-ton revolving-type shovel, m
on traction wheels, dug 3-ft wide trenches in sandy, cavi
It was supported on a platform in 3 sections, which, as the
moved forward, were carried ahead by hooking them to the dipper. A 70-ton
supported on rollers on a 38 by 24-ft platform, excavated trenches 16 ft wide i
firm clay, loading into dump cars. The shovel was moved forward by a cable a
to a deadman. The excavation was made in 2 benches, the first 10 ft and the sec
ft, in order to obtain fine material for back-filling. Costs of this shovel work
follows. 25-ton shovel: cost per day, $19.21; cu yd per day, 80; cost per cu yd,
actually digging, 35.8% of working time. 70-ton shovel: cost per day, $38.10;
per day, 569; cost per cu yd, 6.7¢; actually digging, 44.9% of working time.

Traveling derricks, land dredges, and locomotive cranes, usually
ahead of the trench or along one side, though they may straddle it.

A 1-cu yd orange-peel bucket, on a full-swing roller-mounted derrick, used in
by city forces, cost $20.30 per day for labor of 6 men. Ordinarily it excavated a
cu yd per 8 hr day, all dumped on a spoil bank at one side; hence, labor cost was
cu yd. 50 lb dynamite @ 15¢, and 0.75 ton coal @ $3, were used per day, mak
field cost of 6.6¢ per cu yd, excluding wear and tear. For this work the swinging
with orange-peel bucket was better than a steam shovel, since it could work

... These were 11 ft apart. With the derrick the soil could be deposited far ... from the trench to make rehandling unnecessary. A steam shovel would have ... temporary bracing, followed by permanent bracing, and its boom would be too ... to deposit the soil the necessary distance from edge of trench.

Ditching by explosives, if properly done, will excavate and spread the ... over a distance, and is economical in dry or wet ground, or soil under ... The flow of water is depended upon to clean out the bottom. In stiff ... hardpan, holes should be 26 in apart, in loose mucky soil, 30 in apart, ... are punched or bored to within 6 in of desired depth of ditch. Strongly ... soil is cut with a spade along side lines. For methods of charging and ... dynamite, see Sec 5, Art 7.

... are best blasted simultaneously with a magneto; or placed 18 to 24 in apart and ... by concussion from a middle hole, detonated by fuse and cap. Table 22 gives ... charges. 20% dynamite is ordinarily used, or 40% in stiff, tenacious soil. For soils ... at top and hard at bottom, use 40% dynamite in bottom of charge and 20% above.

12. Excavating Frozen Earth and Hardpan

Bank blasting. In hard, cemented deposits, dynamite is better than black ... in soft ground, the latter is more economical. With very high banks ... toes should be blown out and the top allowed to drop. Charges should ... so that the line of least resistance is horizontal. With banks 50 to ... high in cemented gravel, the length of main drift should generally equal ... height of bank. Cross drifts are driven parallel to the bank face, their ... depending on length of face to be blasted. Powder charge for aver con- ... is about 4 lb per cu yd of ground to be broken. (For further details, ... 5 Art 7, Table 14, Cases 12–16.)

... at the property of the Milton Mining and Water Co, Sweetland, Cal, during ... required an aver of 0.382 lb Judson powder per cu yd (3). The top gravel had ... washed off, leaving banks (usually hard and cemented for 50 ft, but soft above) from ... to 85 ft high. In some parts, 8.3 to 8.5 cu yd were shattered per lb of powder. ... clay, loam, conglomerates, marl, etc, difficult to pick, blasting may be economical. ... ate by picks until a face is formed, and make vertical 1.5 to 2.25-in holes in a ... of the face with pointed bar, churn drill, or auger. Depth of holes should ... less than the height of bank, distance between them being 1.5 times line of least ... (Sec 5, Art 5). In the formula $B = CR^3$, B = charge in oz, and R = line of ... resistance in ft; the "rock coeff" C should be determined by trial. For loam, con- ... and ordinary soil, using 30% dynamite, C is usually nearly 0.6. Holes in ... ground should be "chambered" (2).

Thawing frozen ground may be done by burning gasoline or coal oil, or
of lime, steam jets, or wood fires. In northern Minnesota, where earth fre
a depth of 4 or 5 ft, frozen earth is softened, where pole holes are to be d
pouring in a cupful of gasoline or coal oil and igniting it. Use of 1 gal of oil p
reduces cost of digging 15%. C. P. Chase states that ground frozen to 4
hard to be excavated by a trench machine, was softened sufficiently by spre
small pieces of lime along the line of proposed trench, covering them with m
or straw, and pouring on hot water to slack the lime and liberate the hea

An economical mode of thawing earth for digging trenches is to use open-end w
boxes 12 by 24 in by 16 ft; 4 of them are placed end to end, with joints wrappe
gunny sacking or canvas, and are covered with earth. 2 rows of boxes are set side
over the site of the trench and filled with steam from a boiler. Thawing has thu
done for 1.75¢ per lin ft of trench. For digging post or pole holes, a steam jet pip
be forced down, 2 men being able to thaw about 30 holes in 10 hr.

Cost of trimming and dressing frozen ground on R R construction is thus
About 1 500 ft of roadbed had to be dressed for laying track, 2 300 sq yd of surface
in cut and 900 in embankment. The cut was within a few in of grade throughc
aver of 1 in being trimmed off the surface, amounting to 100 cu yd. 133 cu yd w
cavated by ditches. Only a few places on the fill had to be cut down, the low
being raised with stuff from the cuts. The ground was frozen to about 1 ft deep.
was as follows: foreman, 9.5 days ($31.67), 1¢ per sq yd; labor, 145.5 days ($218.25)
carts, 15 days ($52.50), 1.6¢; total, 9.4¢ per sq yd. Usual cost of trimming on R R
is about 1¢ per sq yd. On this work each man trimmed and dressed 22 sq yd pe
while under favorable conditions he can do about 6 times as much. Each man lo
and shoveled 1.5 cu yd per day. Total cost per cu yd was $1.30. Picks could not b
to advantage except in ditches, and most of the soil was cut with mattocks, 10
pickers being required to keep 3 or 4 shovels busy loading (1).

13. Embankment

Dumping. Earth dams and dikes should be built in horiz layers, but
embankments are usually made by dumping from cars traveling on temp
trestles, and are built up from ends and sides. When filling in old trestl
may be necessary to spread the soil evenly when dumped, to prevent the t
from being thrown out of line.

Unloader plows (ballast unloaders) used to scrape or plow the earth from flat
They are built of steel in 3 general types: center, right-hand, and left-hand plows.
are usually drawn over the tops of cars (after the wheels have been blocked) by a
attached to the locomotive. The Lidgerwood unloader uses a cable from a 10 by
hoisting engine mounted on the first car. Price of unloaders, $300 to $650. A 1
train can be unloaded in 10 to 30 min on straight track. On curves the cable mu
guided by snatch blocks, and unloading requires more time.

Spreading. A man can spread 4 to 10 cu yd (aver, 7.5 cu yd) of earth
hr, 5 to 8 cu yd of gravel or hardpan, and about 2.5 cu yd of mud. A
grader, such as a Shuart or Twentieth Century, with team and driver,
spread up to 50 cu yd per hr, but must have room for the team to operate.
road machine, with 3 teams, driver and helper, will spread 90 cu yd per h
6 in layers, provided there is plenty of room. Under certain conditions e
can be spread efficiently by hydraulicking (Art 10).

Railroad grader is a machine, mounted on standard-gage trucks, having wings a
sides which spread and grade the earth after it has been dumped from cars. A 2
25-ton locomotive is required to pull the grader. Weight, 6 500 lb; cost, $3 000 (11)
train load of 150 to 200 cu yd can be leveled in 8 min sufficiently to clear passing tr
and leveled down to 2 ft below the rail in 10 to 15 min. From 1 000 to 2 000 cu yd
day can be handled. Upkeep cost per day: Depree on $5 000 machine (15-yr life,
days per yr), $1.11; int @ 5% on $1; repairs, $50 per year, 20¢; 1 operator, $2.50;
waste, etc, 10¢; locomotive and crew, $5.; total $10.13.

Sprinkling and rolling embankments for reservoirs is done with grooved rollers. The material must be thoroughly compacted, to avoid future settlement and obtain max- it is usually spread in 6-in layers, soaked with water, and well rolled. 3-horse ... holding 150 cu ft of water, can sprinkle 333 cu yd in 10 hr. Cost of sprinkling ... embankment employing 3 wagons was 2.25¢ per cu yd, 5 cu ft water being used ... Men with hose will usually be more expensive, but this depends on thorough- ... the sprinkling. On a reservoir embankment, made by dump wagons loaded by ... shovel, 12 men were employed on the dump (mostly for picking out stones) and ... and 2 men on a light Austin leveler. Sprinkling was done from a line of 1-in ... with valves every 50 ft. Daily labor cost is given as follows (1): 1 craneman, $4; ... fireman, $3; 1 fireman, $2; 1 pit boss, $2.50; 4 pitmen @ $1.50, $6; 19 teams on ... @ $3.50, $66.50; 2 teams on leveler, $7; 12 men on dump @ $1.50, $18; 1 man ... $1.50; 1 water boy, 50¢; 1 foreman on dump, $3.00; total, $114. At 800 cu ... output, cost of labor and fuel was about 15¢ per cu yd of excavation. To this ... added int and deprec of plant, and cost of moving shovel. This cost is unusually ... reservoir work.

Puddle is a mixture of clay and gravel, wetted and rammed or rolled into a dense mass, ... percolation of water.

... 1 will make 1.3 cu yd, or 1.25 cu yd when thoroughly rolled; formula 2 will ... 16 cu yd, and 1.2 cu yd when rammed. When clay can not be obtained, very fine ... some loam may be used to fill the voids ... Clay alone is sometimes preferred. ... puddle is used in confined places it must be ... concrete and rammed by hand. With ... at $1.50, the cost of mixing and placing ... 10 to 60¢ per cu yd. When covering a ... the gravel should be spread 3 in thick, ... spread over this, and sand on top. The ... mixed by harrow and team, then watered, ... with a 2-ton sectional roller. With labor ... and teams at $3.50, spreading by hand ... per cu yd, harrowing 5¢, sprinkling 2¢, and ... 6¢, total, 20¢.

Table 23. Proportions for Puddle

... cost, lin ft.	1.74	1.51
... cost, lin ft.....	3.04	2.73

A pile trestle for building a concrete pier at Superior Entry, Wis, cost $16 per M for lumber and $3.25 per M for labor of framing and erection, exclusive of foundation piles. It was built each side of the proposed pier, 3 023 ft long.

Table-supported track and dumping platforms may be used where the ground to ... is too soft and yielding to carry a trestle, or where the required height of a trestle ... make the cost prohibitive. Two of these were used on the Lake Erie & Pittsburg ... One was 1.25 mile long, for a 30-ft embankment on a marsh. First attempt at ... was by laying crossed timbers on the muck surface, piling brush upon this grill- ... dumping trains from this. After being extended 600 ft, the entire work sank ... ft of water. A trestle built for the same distance became badly deformed after ... use. The third method was as follows: Two 1⅝-in steel cables, at 5-ft centers, ... stretched from the fill already made over the nearest remaining trestle bents to the

...ber bents. Th... ...ese cables ties and nails were laid. Cable towers eventually w... ...ad the trestle ... Trains of 7 cars (4-cu yd) were run on the cables, loading ... ...00 cu yd per ... ... of 2 shifts, most of the material being dumped by day shift. ... near Cleveland, O. ... method was used for making a fill across a 400-ft gorge, 95 ft deep. ... was 2 small ... ...e bent on each bank and a tail bent in the center. Two 1 1/16-in ... ...anized cables, 7 L... ...part, provided with turn buckles, were stretched over the bents and ... ...ored to dead-me... ...of buried logs. Ties for the rails were fastened to the cable by ... ...bolts. Small trest... ...bents were put in as the fill advanced. Table 25 shows the cost.

Table 25. Comparative Costs of Cable Roadway and Trestle

Actual cost of series cable roadway:		
2.25-in galvanized bridge cable, 1 000 ft		$600 00
Eyebolts, 2 5 in diam, with clevises for both ends		108 30
Turnbuckles (2) at 00		120.00
Chains (2) at north end		67 40
Cast washers (4), 8-in d		1 46
Timber for A-frame (a	tained on ground):	
upper 42 ft, 24 ft by	g and cross ties, 3 800	
ft, at $34 per M		108 80
Lower 50 ft of A-fra	ng, rough in tree	32.00
Team work for hauli	ring timber for erection	65.00
Carpenter labor on	bank	231 40
Time of supt, getting on	work in general	60.00
Common labor, for digging trenches,	and erecting cableway	112.00
Nails and iron in A-frame and bents		29.40
Total cost of cableway		$1 531.76
Estimated cost of timber trestle:		
Timber (all uprights, planks for bracing, stringers, etc), 98 000 ft @ $26 per M		$2 548.00
Labor, @ $6 per M, $588; spikes, $98; drift bolts, $40		726.00
Total cost of trestle		$3 274.00
Balance in favor of cableway		$1 742.24

1. Chemistry of Explosives

Underlying principles. The power of an explosive to do work depends upon the facts: (*a*) that a small volume of explosive is capable, under certain conditions, of changing into a large volume of gas at high temperature, and (*b*) that this change takes place almost instantaneously, resulting in the development of great expansive force at the moment of explosion. In the case of black blasting powder, a mixture of sulphur, charcoal, and sodium or potassium nitrate, the nitrate supplies oxygen for combustion of the sulphur and charcoal. The decomposition of black powder, once started, therefore proceeds without need of oxygen from the air. The case is somewhat different with nitroglycerin, a compound of carbon, hydrogen, and nitrogen, which is explosive in itself without requiring admixture with other substances. When detonated, it is decomposed into CO_2, nitrogen, and water, which at the high temperature of explosion and at atmospheric pressure occupy about 1 000 times the volume of the original nitroglycerin.

Ingredients and their properties. The common ingredients of high explosives are given in Table 1. The term "explosive base" in column 3 covers, besides compounds explosive in themselves, certain compounds which are not explosive alone, but become so when sensitized by some such substance as nitroglycerin.

Note.—Throughout this section, nitroglycerin will generally be designated by N G, and other ingredients of explosives by their chemical symbols.

Table 1. Ingredients of High Explosives

Ingredient	Chemical symbol	Function	Remarks
Nitroglycerin	$C_3H_5(NO_3)_3$	Explosive base	Liquid, highly explosiv
Nitrocellulose (guncotton)	$(C_6H_7(NO_3)_3O_2)_x$	Explosive base and gelatinizing agent	Solid, highly inflamma and explosive when
Nitrostarch	$(C_6H_7(NO_3)_3O_2)_x$	Explosive base	White powder, highly flammable and explo when dry
Organic nitrocompounds	.....	Explosive base, but used primarily to reduce freezing point	Some solid, others liq the higher nitro-c pounds explosive, lower non-explosive themselves
Ammonium nitrate	NH_4NO_3	Explosive bases and oxygen carriers	Solid, not explosive alo very soluble in water
Potassium chlorate	$KClO_3$		Soluble in water, hig explosive when mi with combustible mat
Potassium perchlorate	$KClO_4$		Difficultly soluble in wat highly explosive wh mixed with combustil matter
Sodium nitrate	$NaNO_3$	Oxygen carrier	Soluble in water, not exp sive alone, deliquesce
Potassium nitrate	KNO_3	Oxygen carrier	Soluble in water, not exp sive alone, not deliqu cent
Wood pulp	.....	Absorbent and combustible	Best combustible absor ent; in highest grad equal to kieselguhr i absorbent capacity
Wood meal	.....	Absorbent and combustible	Fairly high absorbent capacity
Ground coal	.....	Combustible	.....
Charcoal	.....	Combustible	.....
Flour	.....	Combustible	.....
Sulphur	S	Combustible	.....
Chalk	$CaCO_3$	Antacid	.....
Zinc oxide	ZnO	Antacid	.....
Kieselguhr	SiO_2	Absorbent	Has no value except as absorbent

Reactions. When carbon burns in presence of an excess of oxygen CO_2 is ... if there be insufficient oxygen for complete combustion, CO also is ... When carbon in lumps burns in air, combustion is slow; but if in ... the reaction is very rapid, and may result in explosion. The in... of black blasting powder (S, charcoal and niter) are finely ground, and ... ghly incorporated, to bring all parts of the combustibles into close con... with the oxidizing ingredient, thus favoring rapid and complete combustion.

When black powder explodes, the reaction is:

$$2\,KNO_3 + 3\,C + S = K_2CO_3 + K_2SO_4 + 3\,K_2S_2 + 14\,CO_2 + 10\,CO + 10\,N_2$$

	Charcoal	Sulphur	Potass carbonate	Potass sulphate	Potass trisulphide	Carbon dioxide	Carbon monoxide	Nitrogen
	Solid	Solid	Solid	Solid	Solid	Gas	Gas	Gas

...plosion is accompanied by evolution of heat, which expands the gases to ... large volume, resulting in high pressure.

When nitroglycerin explodes, the reaction is:

$$4\,C_3H_5(NO_3)_3 = 12\,CO_2 + 10\,H_2O + 6\,N_2 + O_2$$

	N G	Carbon dioxide	Water	Nitrogen	Oxygen
	Liquid	Gas	Vapor	Gas	Gas

...ense rapidity of this change is illustrated by the fact that, if a pipe 5 ... long were filled with N G, and a blasting cap were detonated at one end, ... column would be converted into gas within about one second.

Dynamite consists essentially of a mixture of $NaNO_3$, wood meal, and N G. $NaNO_3$ may be replaced by KNO_3, the wood meal by flour or sawdust, and ... a portion of the N G by other organic compounds or by NH_4NO_3. The ... ingredients are not so finely divided as those of black powder, nor so thor... incorporated; hence, the mixture would not burn so rapidly except for ... N G, the extremely rapid explosion of which so accelerates combustion of ...her ingredients that the whole mixture explodes much faster than black ...der. Taking a dynamite of the composition: N G, 40%; $NaNO_3$, 46%; ... meal, 14%; and assuming that wood meal has same ultimate composition ...s cellulose $(C_6H_{10}O_5)_n$, the reaction of explosion is:

$$4\,C_3H_5(NO_3)_3 + 6\,NaNO_3 + C_6H_{10}O_5 = 9\,CO_2 + 6\,N_2 + 10\,H_2O + 2\,O_2 + 3\,Na_2CO_3.$$

Gaseous products of explosion. When explosives detonate, they usually ... a mixture of solid, liquid, and gaseous products. The solid products may ... sodium or potassium carbonate, sodium or potassium sulphate or ... where sulphur is present in the explosive, and calcium carbonate, etc. ... all explosives, except black powder, form large quantities of water, be... vapor at moment of detonation. Smoke consists of the solid products ... divided state. Gaseous products are of most importance to the miner, ... they determine character of fumes after a blast, and provide the ruptive ... For products of different explosives, see Sec 23, Art 3, Table 3.)

With the Bichel pressure gage (2), it is possible to detonate an explosive in a closed ...er, to withdraw a sample of the gases formed by the explosion, and to determine ... composition. The gases produced by a 40% straight gelatin under these conditions ... approximately the following composition, as determined experimentally: CO_2, ... 12%; O_2, 1%. The composition of the gases varies with different explosives. ...me cases there is a small amount of free O_2, as in example cited above; in others, ... O_2 but varying amounts of CO and H_2. CO is poisonous, and serious or even fatal ...urances may result from the use of explosives which produce large amounts of this ... places where ventilation is poor.

Character of fumes from an explosive is affected by conditions under explosive is used. When dynamite BURNS instead of detonating the fum entirely different from those formed by detonation, and contain large an of oxides of nitrogen and CO, both poisonous. Burning of dynamite in a hole may result from improper mode of charging; for example, if the f passed through a cartridge, the dynamite may be ignited by side-spit from fuse. Blown-out shots are apt to produce noxious fumes; well-t shots are least apt to yield them. When dynamite is so charged that ma amount of useful work is done, the fumes are least harmful.

2. High Explosives

General classification of explosives. There are two general classes: (different types of black blasting powder, and (*b*) high explosives. powder is a mixture of combustible and oxidizing ingredients, no one of is explosive alone; high explosives always contain an ingredient which plosive in itself, at least when sensitized by proper means. Because o difference in composition, high explosive detonates with much greater ra than black powder; hence, the great rending and shattering effect of explosive, even when unconfined. It is a common idea that high expl "shoot down," while black powder "shoots up." This fallacy arises fro fact that the slow black powder, when exploded unconfined on top of a r other object, does no damage to the rock, but dissipates into the air; whi quicker high explosive, under same conditions, may break the rock be it, even without confinement other than that of the atmosphere. All expl exert equal pressure in all directions.

Properties. The different types of high explosives vary widely in properties. Some are exceedingly quick, others relatively slow, still o intermediate in quickness. Different types of explosive also vary in de from the heavy gelatins to some of the coal-mine powders, which are light. High explosives are graded according to their strength compared straight dynamite, which is the only type containing actual percentages of The other types make up their strength by such explosive substances as substitution compounds, explosive salts, and guncotton. High explosives taining no N G are graded the same way as "40% strength."

Straight dynamite, containing only N G, $NaNO_3$, wood meal, and an an (Table 1) is taken as standard because it is the simplest and best known ty high explosive in the U S. It is more or less pulpy, easily crumbled wrapper is removed, obtainable in different strengths up to 60%, very q fairly waterproof, and the most sensitive of the dynamites. A 50-lb case tains 100 cartridges 8 in sticks. Straight dynamites are suitable for work requ strength and quickness where water conditions are not too severe; not re mended where ventilation is poor. Freezing point, usually from 42° to 4

Ammonia dynamites have explosive base consisting of N G and NH_4 They are of same strengths as straight dynamites, but slightly slower and sensitive, do not easily ignited by flame, and, hence, not liable to be lighte side out of fuse. Because of the solubility of NH_4NO_3 in water, they req more care in wet work than straight dynamites.

Ammonia gelatins are similar to straight gelatins in composition and properties. Their explosion products are especially free from noxious fumes; hence, they are recommended for confined work.

Table 2. Classification of High Explosives

Principal types		Essential ingredients
Straight dynamite		Nitroglycerin, sodium nitrate, and wood pulp or other combustible material
Ammonia dynamite		Like 1, with addition of ammonium nitrate
Straight gelatin		Nitroglycerin, nitrocotton, sodium nitrate, and wood pulp or other combustible material
Ammonia gelatin		Like 3, with addition of ammonium nitrate
Blasting gelatin		Nitroglycerin and nitrocotton
Granulated dynamite		Sodium nitrate, sulphur, and coal, sensitized by nitroglycerin
Permitted explosives for coal mines	High-combustible class	Nitroglycerin, sodium nitrate, and high percentage of wood-pulp or other combustible material
	Ammonium nitrate class	High percentage of ammonium nitrate, with low percentages of nitroglycerin and wood pulp
Explosives not containing nitroglycerin	Ammonium nitrate class	Ammonium nitrate, with small amount of organic nitro-compounds
	Nitrostarch class	Nitrostarch, sodium nitrate, and combustible material
	Chlorate class	Potassium chlorate or perchlorate, with organic substances

Note. — Low-freezing modifications of nearly all dynamites and gelatins are also on the market. They have same essential composition as the above, with additional ingredients which cause them to remain unfrozen for a long time at temperatures far below the freezing point of other nitroglycerin explosives.

Blasting gelatin is a tough, elastic, jelly-like mass which, except for 1% of antiseptic, consists entirely of N G and guncotton. It is the strongest and most powerful of all explosives. When loaded to fill drill-hole completely it is excellent for hard rock, especially where large holes can not be drilled. Owing to its elasticity it is difficult to make it fill the holes completely; whence, a loss of efficiency. Best results are obtained if explosive is charged with wrappers which can then be pressed in to fill the hole, without so much tendency to spring back and leave unfilled spaces. When soft and plastic, blasting gelatin is no more dangerous than other explosives, but when frozen it should be handled very carefully. It is dangerous to break frozen sticks of blasting gelatin.

Granular dynamites are mixtures of $NaNO_3$ and combustible dope in form of hard grains with a small percentage of N G. They are free running, especially the lowest grade, such as R R P, containing 5% N G, which is in grains nearly corresponding in size to FF

blasting powder. R R P dynamite is usually packed in paraffined bags, containin
Granular dynamites are slowest of all dynamites, approaching black powder mo
than other high explosives; not well adapted for wet work, but resist water be
black powder; especially useful for stripping work, and for loosening sand and e

Coal-mining explosives. Special "short-flame" explosives should in collieries containing dangerous amounts of inflammable gas or dust. explosives have been largely developed during the past few years, an now on the market can safely be used under proper restrictions. Thei facture began in Germany about 1886; in U S, 11 300 lb w in 1902; in 1913, 27 685 770 lb, of which 21 804 285 lb were used in col

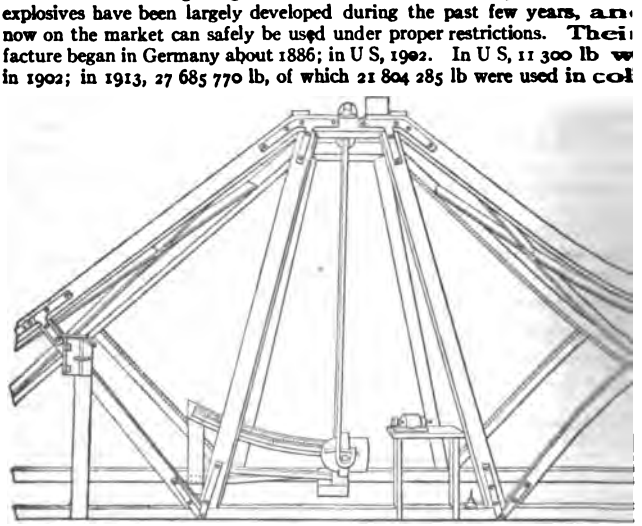

Fig 1. Ballistic Mortar

"Permissibles." At the Pittsburg testing station of U S Bureau of Mines mining explosives are tested to determine whether they meet definite requireme safety in "fiery" mines. Those which pass the prescribed physical and chemica are classed as "permissible" explosives (19), lists of which are published from t time. The tests include the firing of "blown-out" shots into explosive mixtures and air, coal dust and air, or gas and dust with air, in a large steel gallery (Fig 2) plosives which do not cause ignition of such mixtures, and which are also satisfact to chemical composition, stability, sensitiveness, and volume of poisonous gases ev are considered "permissible," when used under prescribed conditions. These expl are recommended by U S Bureau of Mines for use in collieries, and in some states quired by law for dangerous mines. Bureau of Mines bulletins describe meth testing, results, and fees for testing explosives (19).

Classification of permissible explosives in the U S: (*a*) ammonium-nitrate sives, containing NH_4NO_3 as chief ingredient, are insensitive to shock, free from lia to ignition from side-spit of fuse, and produce small amount of noxious fumes; (*b* drated explosives, in which the desired reduction of temperature results chiefly fro water of crystallization of salts included in their composition; (*c*) explosives of th ganic-nitrate (other than N G) class include nitrostarch explosives; (*d*) nitroglyc class comprises those containing N G which are not included in the other cl These are deficient in oxygen, thus producing much CO, instead of CO_2, but are prefe in wet mines. In each class are explosives of widely varying properties, and the sele of a suitable "permissible" depends largely upon local conditions.

High explosives not containing N G usually contain no liquid ingred which can freeze, a decided advantage in cold climates. They are usually l

plasticity, are often somewhat dusty, and have the disadvantages of low low strength, and low sensitiveness. They can not be used indiscriminplace of N G explosives, but are useful for special purposes.

Low-freezing explosives are similar in properties to other high explosives, resist freezing at temperatures considerably below freezing point of N G; remain unfrozen for days or weeks at temperatures as low as 0° F. More and skill are required in making low-freezing dynamites than regular dyna- and since many grades are on the market, some of doubtful merit, their can requires special attention.

Testing high explosives. While laboratory tests, however elaborate, can not entirely practical field tests, in determining relative value of different explosives for any

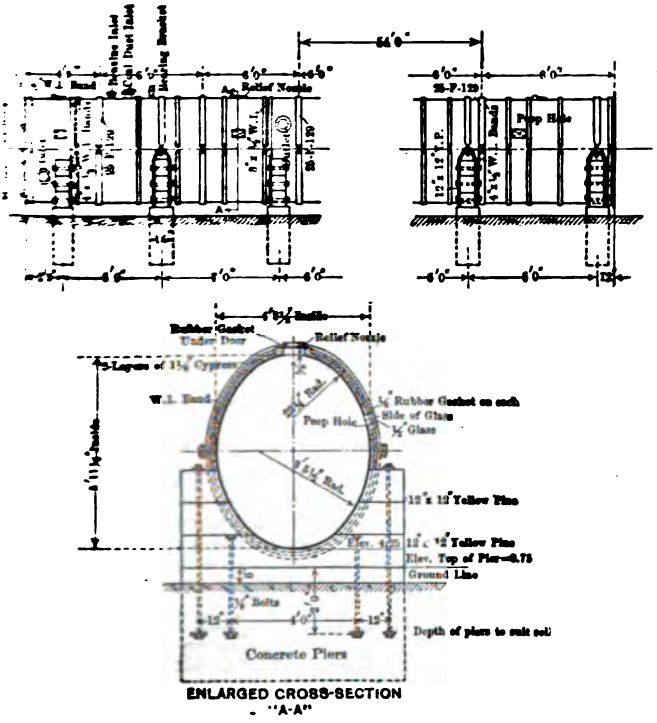

Fig 2. Testing Gallery

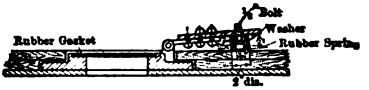
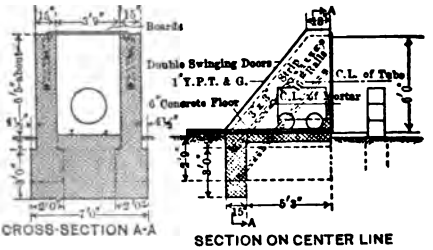
similar work, they can aid in selection, if carried out with suitable apparatus and by expert persons. No single apparatus or test is sufficient, since the practical value of explosive depends upon many factors. Some of the more important factors, determined in a well-equipped laboratory, are:

1. **Power**: determined in the ballistic mortar (31) (Fig 1) or in the Druckmesser.
2. **Brisance, or velocity of detonation**: determined by the Bichel (2) or the Dautriche (35).

STRENGTH AND QUICKNESS combined: determined by the Trauzl lead block t and 34). (Note. For a discussion of the Druckmesser, Trauzl, and ballistic morta with comparison of results, see Bibliog 32.)



SECTION SHOWING RUBBER SPRING OF RELIEF NOZZLE.



CROSS-SECTION A-A

SECTION ON CENTER LINE

Fig 3. Detail of Mortar Housing for Testing Gallery

SAFETY in gaseous and dusty mines: determined by means of the testing galle (Fig 2 and 3).

OTHER FACTORS are: propagating power, density, resistance to water, resista freezing, stability, and sensitiveness to impact.

3. Black Blasting Powder

"A" blasting powder (saltpeter) is made from KNO_3, charcoal, an phur, in the approximate proportions of 75, 15, and 10. It is used mai quarrying, for blasting hard dimension stone, and for work in damp clima

"B" blasting powder (soda) is made from $NaNO_3$, charcoal, and su in the approximate proportions of 72, 16, and 12. Because of its lowe "B" powder is more commonly used than "A" powder, and is sufficiently for most of the purposes for which black powders are used. Owing to quescent property of soda niter, "B" powder is less desirable for use in climates, and for long transportation or storage.

Important properties. Black powder is not made in different strengt dynamite, but varies in quickness, depending upon size of grain. Classes and "B" are of different granulations. For "A" powder the common are C, F, FF, and FFF; for "B" powder, CCC, CC, C, F, FF, FFF, The CCC grains, representing largest size, are about ½ in diameter; grains, the sma lest, are about $\frac{1}{16}$ in diameter. Fig 4 shows the different

The finer granulations are quicker than the coarser, and are used for bl rock, refractory materials, and coking coal; the coarser granulations ar and are used for other coals, shale, and earthwork, or wherever it is des to heave out the material in large pieces, instead of shattering it. (See A Blasting powder is either glazed (polished) or unglazed. Glazed pow brighter, and more free-running than unglazed, and is more generally Glazing does not increase efficiency, and produces more smoke. The s

of black powder varies from 1.5 to 1.9, usually about 1.8. High specifi results from compressing the powder to smaller bulk, with consequen

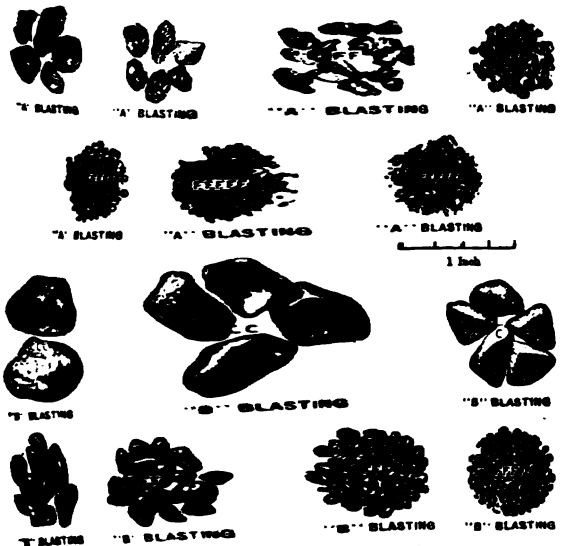


Fig 4. Standard Sizes of Black Powder Grains

action of air-spaces in the grain. Black powder is unaffected by cold, bu little resistance to water, since niter is readily soluble.

4. Transportation of Explosives and Blasting Supplies

Transport by rail. A shipper of explosives should be familiar with loca ordinances, state and federal laws, and the regulations of the Interstate Com merce Commission. By Act of Congress, March 4, 1909, effective Jan 1, 1910 the Interstate Commerce Commission has power to regulate interstate trans of explosives. These regulations specify that explosives to be shipped by rail must pass certain tests for stability and sensitiveness, that container shall stand specified tests for strength, and that cases and contents be packed in a prescribed way. Hence, nearly all manufacturers of explosives doing rail business make and pack all their product to comply with the regulations Printed copies of regulations in pamphlet form are obtainable on request fro the Bureau of Explosives.

Explosives which can not be shipped by rail include:

1. Liquid nitroglycerin.
2. Dynamite containing over 60% N G (except gelatins); see Table Nos 3, 4, and 5.
3. Dynamite having an unsatisfactory absorbent, or showing signs o leakage of N G.

4. Nitro-cellulose in a dry condition, in quantities over 10 lb, in o side package.
5. Dry fulminates in bulk.

The matter of forbidden explosives is of interest to the user mainly in con with the condition of his stock, in case reshipment is necessary; then above becomes important. Dynamite stored for a great length of time, o adverse temperature conditions, occasionally exudes N G, and becom for rail transport. With proper storage, reasonably rapid movement o and care to use old stocks first, this condition should not arise. If ne to ship by rail explosives not acceptable under Interstate Commerce Com regulations, these explosives may be repacked only when authorized by of Explosives. No explosives in broken or damaged packages should be for rail shipment. The aforementioned Act of Congress makes it a c offense to ship explosives on common carriers carrying passengers for hir offer for shipment any explosive under deceptive markings.

Explosives which must not be shipped together. The Bureau plosives publishes a chart showing the explosives and other inflammable which must not be shipped together. A specially important regulation blasting caps must not be shipped or stored with high explosives.

Condition of cars. R R cars in which explosives are shipped must b fully inspected, and must comply with certain specifications. They must certified and placarded in uniform manner, as well as loaded and brace specified way.

Carload shipments. The Interstate Commerce Commission regul permit shipment in one car of not more than 70 000 lb gross weight of expl The minimum quantity taken at carload prices varies with different ra and in different parts of the country, ranging from 17 500 to 30 0 Consignee must remove shipment of explosives from carriers' property 48 hr after notice of arrival at destination; many railroads allow only

Shipment by boat. Navigation laws must be complied with, also all regulations in regard to authorized docks and quantities which may be unl Regulations prohibiting transport of caps with dynamite should apply wh the vessel is under Interstate Commerce Commission jurisdiction or not it is permissible on large vessels, in certain cases, to carry caps in special partments entirely separate from the cargo of high explosives and at saf [illegible] thereon.

Shipment by wagons. Special care should be taken that equipment [illegible] of explosives is in good condition and not likely to break [illegible] Never overload wagons. Wagons intended for regular tran [illegible] explosives should have springs and sides or body should be lined with b [illegible] Explosives may be t [illegible] body is covered with boar [illegible] explosives.

4. Shipping Containers

Black blasting powder [illegible] shipped in kegs of two sizes, k [illegible] powder, or in 5-lb cans [illegible] anthracite coal fie [illegible] powder. Two "sl

... of powder) are packed together in a long can. Gross weights of more ... packages of black powder are:

... lb keg with contents	Approx	gross	wt	27¼	lb
... lb " " "	"	"	"	13¾	"
... lb cans, with contents and shipping box	"	"	"	135	"
... lb can, with contents in two cartridges	"	"	"	29	"

High explosives are shipped in cylindrical cartridges, about 8 in long and ... in diameter. Cartridges are usually packed in wooden boxes or cases, ... 50 lb to the case. Character of cases, as to strength, thickness of wood, ... construction, is regulated by Interstate Commerce Commission. The ... of cartridges of each size in a 50-lb case is fairly regular for any given ... of dynamite.

Size cartridge	Approx number cartridges per 50-lb case.		
	Straight dynamite	Gelatin dynamite	Colliery powders
... by 8 in	195	174	240
1 " 8 "	150	132	200
1¼ " 8 "	100	88	135
1½ " 8 "	68	63	100
2 " 8 "	42	34	57

Approximate weight per cubic inch:

Gelatin (straight and ammonia)	0.97 oz
...namite (straight, ammonia, and granulated)	0.85 "
...llery powders	0.63 "

Note. — There are some exceptions. Also, there are a few explosives, such as the low ... ited dynamites, which are packed in 12½-lb paper bags, four bags to a case.)

Blasting supplies. Caps are packed in tin boxes, containing 100 caps, and ... boxes in wooden cases of 500, 1 000, 2 000, 3 000, or 5 000 caps. Electric ... and electric squibs are packed in cardboard boxes containing 25 or 50 each, ... these are packed in wooden cases of from 250 to 500 electric caps or squibs. ... fuse is in rolls of two 50-ft lengths; shipped in wooden boxes containing ... 1 000 to 6 000 ft.

6. Storage of Explosives and Blasting Supplies

Explosives should be stored in well-ventilated buildings, erected for the ... Buildings for storage of black powder or blasting supplies should be ... proof; those for dynamite, both bullet-proof and fireproof.

Location of magazine. In selecting a magazine site the local topography ... be considered, and advantage taken of such natural protection as is ... by hills and areas of timber. The magazine should be far enough from ... buildings to minimize danger to life or property through an accidental ... Table 3 gives distances, depending upon quantity of explosives, to ... tained between magazines and inhabited buildings, public railways, and ... highways:

Table 3. Distances for Magazines, American Practice

Quantity of explosive stored, lb	Minimum distance, ft			Quantity of explosive stored, lb	Minimum dist. ft		
	Inhabited building screened*	Public railway screened*	Public highway screened*		Inhabited building screened*	Public railway screened*	
50	120	70	35	10 000	890	535

8 000	850	510	255	.....	.....	.....	
9 000	870	520	260	.....	.....	.....	

* "Screened" as here used signifies that the building containing explosives *is sc* from buildings, railways, etc, by either natural or artificial barriers. *Where such b do not exist, distances should be doubled.*

Table 3 is the result of an investigation of a committee appointed by the expl manufacturers of the U S, and represents conclusions reached after prolonged stu available data. The Bureau of Explosives of American Railway Association has app and applies the distances specified to be maintained between magazines and public ways. When there are specific state laws and local regulations, they must be com with, but if there be none, the table of distances gives the accepted practice. W explosives are distributed among several magazines the distances between maga should comply with the following formula (distances given are for magazines fully tected from each other by natural or artificial barriers; lacking such protection, dist should be doubled): For magazines containing 25 000 lb or under, not less than 10 for magazines containing over 25 000 lb, add 1½ ft for each 1 000 lb of explosives ad When applying Table 3 for location, *if magazines are nearer* than the above distan they should be *classed as one magazine* containing total quantity of explosives store all. Magazines containing blasting caps should never be nearer than 50 ft to *any o* magazine, and if quantity is over 20 000 caps, distance should be at least 100 ft.

Construction of magazines. Dimensions of magazine without aisles:

Capacity	Dimensions	Capacity	Dimensions
5 000 lb	8 ft × 8 ft	25 000 lb	12 ft × 12 ft
10 000	8 × 10	30 000	12 × 14
15 000	8 × 12	40 000	14 × 16
20 000	10 × 12	50 000	14 × 18

...es of these sizes are for temporary use, and should therefore be as small ...e for quantity of explosives to be stored. Such magazines are mainly ... using explosives in 2 or 3 sizes or grades; dimensions are there... for the given quantities, leaving floor space sufficient only to per... to enter magazine when filled to stated capacity.

...ions of magazine with aisle from front to back and cross aisle through ...

...acity	Dimensions	Capacity	Dimensions
... lb	8 ft × 9 ft	25 000 lb	12 ft × 18 ft
...	10 × 12	30 000	12 × 20
...	12 × 12	40 000	14 × 22
...	12 × 16	50 000	14 × 24

Fig 8. Black-powder Magazine

... should always be in charge of one person, who can be held respon... condition of magazine and stocks, and for their proper and safe ...ng.

Rules for dynamite and powder magazines.

Explosives must be handled carefully.

Do not throw down boxes of explosives violently, nor drag them along the floo

Do not open boxes of dynamite or powder kegs in or near magazine.

Do not have in or about the magazine loose cartridges, open boxes of dyna loose powder.

Do not make up primers in the magazine.

Do not smoke, have matches, oil-burning lamps or lanterns, fire-arms or cartri or near, magazine. If artificial light be needed, use electric flashlight or electric

Do not store blasting caps nor electric blasting caps in this magazine.

Store dynamite and black powder separately. Store dynamite boxes flat, top grades and brands showing; store powder kegs on sides with seams down, or o bungs down.

Powder kegs should be rolled over and contents shaken every 2 or 3 months.

Always use old stocks first.

Keep magazine floor clean.

Keep the ground immediately around magazine clear of leaves, grass, trees, s and débris, to prevent fire from reaching it.

Do not allow any shooting in neighborhood of magazine.

Keep the door locked.

No unauthorized person should be admitted to magazine.

Do not keep any steel, or metallic tools or other implements, in the magazine.

See that good ventilation is maintained during all seasons of year.

When repairs have to be made to interior of magazine, all stocks of explosives be removed to safe distance and carefully protected from weather during prog repairs. Before starting repairs in a black-powder magazine scrub floor with If dynamite has been stored in a magazine, any stains on floor should be carefully scr with solution consisting of: ½ gal water, 1 gal denatured alcohol, ¼ gal aceton sodium sulphide (fused) or potassium sulphide.

Rules for blasting-supply magazines.

Store blasting supplies only in this magazine, i e, blasting caps, electric blasting and fuse.

Do not store powder or dynamite in this magazine.

Do not have loose blasting caps, electric blasting caps, nor coils of fuse lying a magazine, nor take them out of original packages until required for use. Keep pac closed.

Open boxes with a wooden mallet, except when lids are screwed on; then use a driver. Do not keep any other metallic tools in magazine.

7. Handling of Explosives and Blasting Supplies

The Interstate Commerce Commission in matters of transportation, and majority of states in framing their laws, recognize that explosives are a mercial necessity, and furthermore that they can be handled with reason safety. Nevertheless, one must always recognize their nature; their fun is to explode. All owners of explosives should require employes to obs rigidly the rules and regulations which experience has shown will best cons safety of the men themselves, as well as of the public.

From cars or boats to magazine. Use only wooden or non-sparking metal too breaking the bracing in cars. Wooden wedges and mallets answer all practical purp Damaged or broken cases or kegs found in shipment should be set aside, and not take magazine with undamaged stock. If damage is slight, the cases or kegs should be t to a safe distance from magazine, or from car, and repaired. If damage is too grea repair, take explosives to point of consumption and use immediately. If broken ridges or loose grains of powder are scattered in the car, they should be carefully s up and removed before proceeding with unloading, and afterwards destroyed. If t

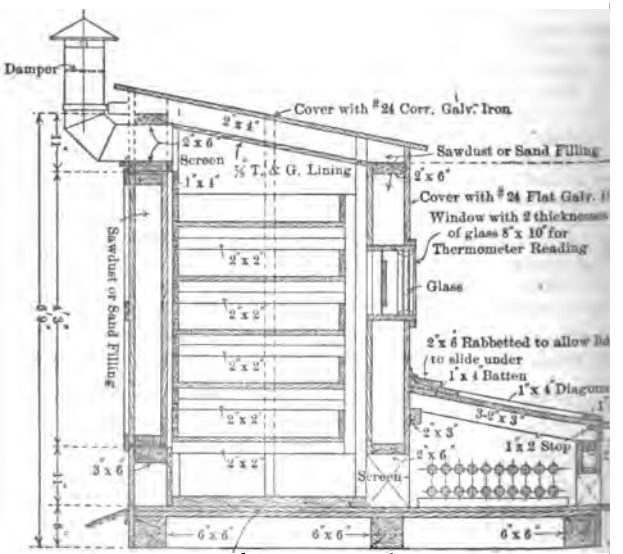
...wing frozen dynamite. If dynamite is frozen it must be thawed before ... freezing point of pure N G is about 55° F, it follows that dynamite

Fig 9. Dynamite Thawing Kettles

...t at any higher temperature. In thawing, it is usually necessary to ...peration somewhat; hence, higher temperatures are used. But ... is readily decomposed by exposure to high temperature. Thawing ...n hot ashes, on top of a boiler, or around a bonfire, is dangerous, and ... to explosion, with possible loss of life. Small quantities of dynamite ...be thawed in a double-jacketed kettle (Fig 9), the dynamite being ...inner compartment, while jacket is filled with water at temperature ... 130° F. Water hot enough to scald the hand is too hot to use. Al- ...l water in separate vessel, and then pour into jacketed kettle. Heat ...ever be applied directly to kettle containing the dynamite. Thawing ... these types are made in two sizes, holding 30 and 60 lb of dynamite.

Dynamite thawing-house heated by exhaust steam. Where large of dynamite are used, a thawing-house should be provided. Fig 10 good type of permanent thawing-house, for 500 lb dynamite at a time, of 50 lb; same construction for larger capacity, size being increased units, with corresponding increase of radiating surface of steam coils. steam is usually the most economical and convenient source of hea steam (steam under pressure) is dangerous, because of possibility of h perature. The area of radiating surface necessary to insure complete varies with climatic conditions. In installing the steam coil, give pipes slope to drain properly. If preferred, same type of coil may be used as designed for hot-water heating (Fig 11). The packing in the walls is eit



SECTION A-A

Fig 10. Dynamite Thawing-house Heated by Steam

or sawdust. Dry sand is good insulating material, but makes ship-lap o and groove boards necessary on outside walls to hold it in place. N coarse gravel for packing on account of missiles which would be throwr of accident to thawing-house. Dry sawdust is probably the best cheap Mineral wool or asbestos fiber gives more perfect insulation, besides be proof, but cost is much higher. A thermometer is placed in back wall of t house, behind a double glass window, so that inside temperature may b without opening doors and admitting cold air. A damper is also place stack to permit regulating the circulation of air through the house. ature of 80° F (27° C) is good for thawing. This house can be built materials at approximate cost of $100. At mines or other works there is enough pipe lying around to make the heating coil, and scrap lumber

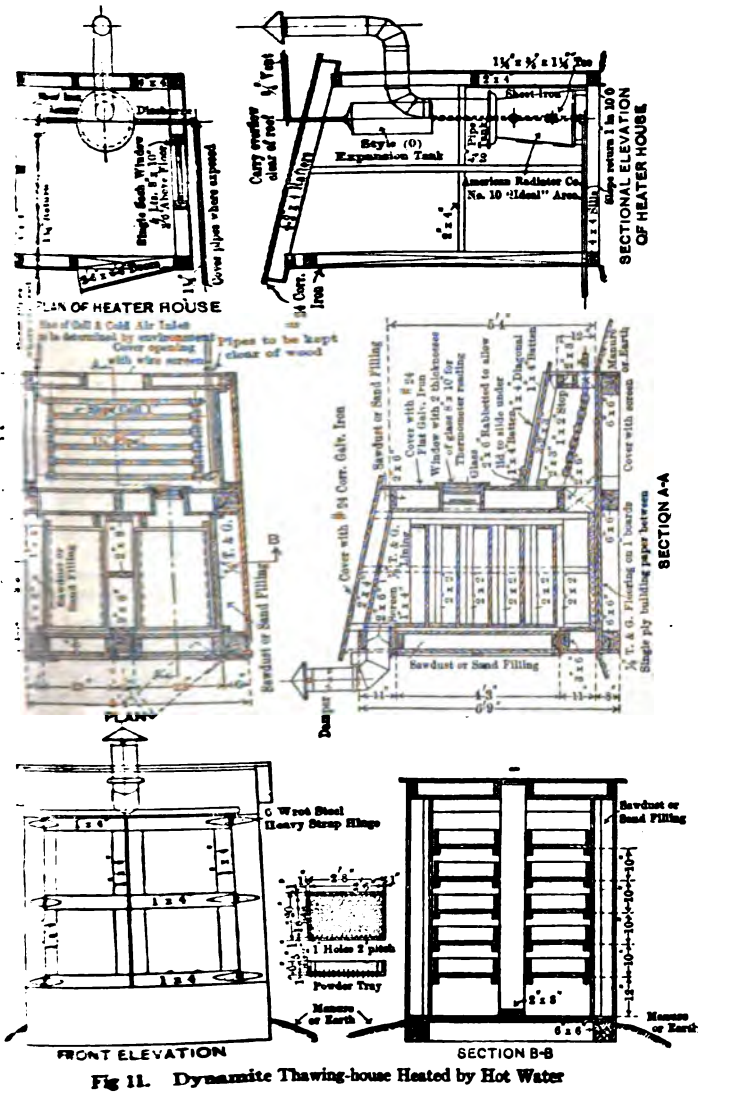


Fig 11. Dynamite Thawing-house Heated by Hot Water

construction, which will materially reduce cost. Note that there is no this house to permit a person to enter, so that it is impossible to use it to prime cartridges. If desired, a small box on wheels can be made

of a size just to hold a certain number of trays from thawing-house. ber of trays needed at one time are placed in the box, covered, and tal work without exposing the dynamite to cold air until ready for chargi

Dynamite thawing-house heated by hot water (Fig 11). This is d thaw 500 lb dynamite at a time, in trays of 50 lb each. For greater capacit size of house in units of 250 lb, with corresponding increase of radiating surfa and size of heater. Construction details are same as of the steam-heated thaw The heater house and standard heating unit for small hot-water systems s Heater house must be enough lower than thawing-house to permit good gr in return pipe to heater. Heater house should be 30 to 50 ft from thawing-hous distance increases construction cost and diminishes economy of operation, whil proximity to thawing-house increases risk. Cover the pipes between the buil standard magnesia pipe-covering, or place them in a sawdust-filled box. Ap cost, when of new materials, $175.

Disposition of damaged explosives. Dynamite to be destroyed should b from magazine in quantities not exceeding 100 lb, to a safe place 400 to 500 from any magazine, and 1 000 ft or more from any dwelling, building, publi railroad; where, in event of its exploding while burning, no damage will be d of boxes should be carefully removed with wooden wedge and mallet, each slit, and the opened cartridges spread upon the ground over as large a spac ticable. To insure proper burning of the dynamite, spread a quantity of str shavings, or excelsior on ground first, on which dynamite is placed. A chain paper, or other material, is then led away from the dynamite to such a distan may be lighted without danger of flame reaching the dynamite before operator position of safety, which should be 400 or 500 ft distant. Explosions sometin even with care, and operator should never remain near the burning explosiv powder may be destroyed by pouring it into a stream or large body of water; t part quickly dissolves and remainder becomes harmless. Cases which have dynamite are dangerous; they should not be used again for any purpose, but burned, using same precautions as described above for destroying damaged dy

To destroy damaged blasting caps, place them, not more than 500 at a hole 2 or 3 ft deep, preferably in sand. Prime a small dynamite cartridge wi electric blasting cap, and place it in contact with the damaged detonators. Fil with sand, and fire with a blasting machine from distance of about 200 ft. D ordinary caps and fuse, as there is danger of premature explosion from spark great care is taken. Before being destroyed, electric blasting caps should h wires cut off an inch or two from capsule, as the wires are liable to cushion the s prevent complete explosion of all the caps. Observe utmost caution in handling caps, as they are extremely sensitive to shock, friction, heat, and sparks.

Precautionary Rules:

Don't forget the nature of explosives; but remember that with proper care be handled with comparative safety.

Don't smoke while handling explosives, and don't handle them near an ope

Don't leave explosives in a field where cattle can get at them. Cattle like tast and saltpetre in explosives, but the other ingredients may make them sick or kill

Don't carry loose caps in the clothing. Keep them in their boxes.

Don't tap or attempt to open a blasting cap or electric blasting cap.

Don't try to withdraw wires from an electric blasting cap.

Don't attempt to take caps from the box by inserting a wire, nail, or oth metallic instrument.

Storing

Don't store or transport blasting caps or electric blasting caps with high explo

Don't store fuse in a hot place, as this may dry it out so that uncoiling will bre

Don't allow priming (the placing of the detonator in dynamite) to be done in house or magazine.

Don't leave explosives, caps, or blasting machines in a wet or damp place. K suitable, dry place, under lock and key, and where children or irresponsible can not get at them.

Thawing

...e frozen or chilled explosives; it is dangerous and wasteful.

8. Charging and Firing Explosives

(See also Sec 5, Art 5, and Sec 6, Arts 8 to 11.)

...ng holes. A drill-hole may be "straight" or "sprung." A straight ... one which is loaded and fired without enlarging. A sprung hole is en... the bottom by exploding in it one, two, or more, successive charges. ...harges are usually not tamped (stemmed). The first charge usually ... of one or two cartridges of dynamite, increased in subsequent charges ...mber is large enough to hold required quantity of explosive. This ... is known as "springing," "chambering," "squibbing," or "burn... Except in soft rocks, slow-acting dynamites are better for springing than ...-acting, as more of the rock is thrown out of the hole and there is less ... to cave and choke up. If sides of hole are very rough, final charge may ... through a tube of brass, tin, or galvanized iron, about 2 ft longer than ... and as large as will fit into it. This prevents cartridges from being ... or smeared along sides of hole. Where a loading tube is not avail... cartridges are usually attached to a sharpened stick, lowered to bottom ... and shaken off.

...ing is the placing of the detonator (ordinary or electric blasting cap) in ...rite cartridge; or placing electric squib or electric cap in a cartridge of ... powder. In priming high explosives, place detonator so that its closed ... its towards bulk of the explosive; that is, if primer is inserted last, the ... should be so placed that its closed end points toward bottom of hole. ...ctor should be so secured that it will not change its position, nor jam ...s of hole, nor come in contact with tamping stick. The wires of an ...ting cap should not be secured in a half hitch; for, when tension is ... current may be short-circuited where wires cross each other. In ... dynamite with cap and fuse, the fuse should never be "laced" or run ... cartridge, because the "side spit" of fuse will often ignite dynamite, ... which will burn, decreasing efficiency of charge and producing noxious ... Top of cap should be imbedded ½ in deep in the dynamite, to cushion ... tamping stick. This small length of fuse will not side-spit before cap ...

...ging. Eliminate all air spaces by slitting cartridges lengthwise with a ...fe and pressing them firmly home, so that they expand and entirely ...ole. Exceptions to this are: (*a*) Blasting gelatin should not be slit, ... plastic that it can not be rammed solidly like other dynamites; (*b*) in ... of coal an air space is purposely left to cushion action of explosive ... prevent undue shattering. Dynamite cartridges, especially gelatins, ...ever be broken, if there is a possibility that some portion of the ex... frozen. They may appear soft on outside and yet have a frozen core. ... such a cartridge may explode it; accidents due to this practice have ...gulation in many foreign countries.

Tamping is necessary for all explosives to develop their full power, required in practically all work except springing a hole (see above). sand, and loam make best tamping. Broken rock, screenings, and o serve fairly well, but are liable to break or cut the fuse or wires.

Wiring for electric blasting. There are three general methods: parallel, and parallel-series connection.

In series connection (Fig 12) one of the wires from first drill-hole is connecte leading or firing line. The other wire is then connected to one of the wires from hole and the other wire of tha of the wires of third hole, and the last hole; the remaining f from that is connected to th leading or firing line. Series tion is necessary when firi ordinary blasting machine. T rent required for series conne at least 1.5 amperes, and the sufficient to overcome resist electric caps. Resistance var length of wires. About one

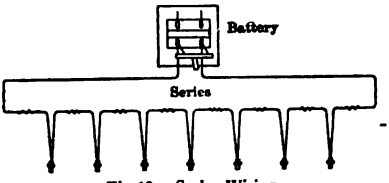

Fig 12. Series Wiring

required for each cap connected in series, although an excess, up to about 440 volt harmful. Too high voltage may cause misfires from short circuits across the ca especially when more than one cap is used in a hole. Direct current is general but alternating current is equally efficient when of a frequency of 60 cycles o and can be used down to 25 cycles. Alternating currents of lower frequency may cause trouble from misfires of the less sensitive caps in the circuit.

In parallel wiring (Fig 13) one wire from each cap is connected to one leading line, and the second cap wire to the other leading line. This method can be used only where a power or lighting current is available, having 1.5 amperes for each

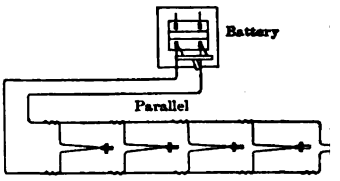

Fig 13. Parallel Wiring

cap so connected. Thus, with 20 caps, firing circuit must have at least 30 a The voltage required is very low. The greater the number of caps in circuit, th the resistance. Assuming resistance of leading wire at 3 ohms and resistance c cap at 1 ohm, the resistance caps in parallel is $(1 + 20) + 3$ or 3.05 ohms. Parallel conn of ordinary electric caps a often used, on account of lar ume of current required.

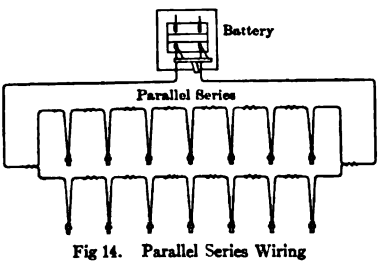

Fig 14. Parallel Series Wiring

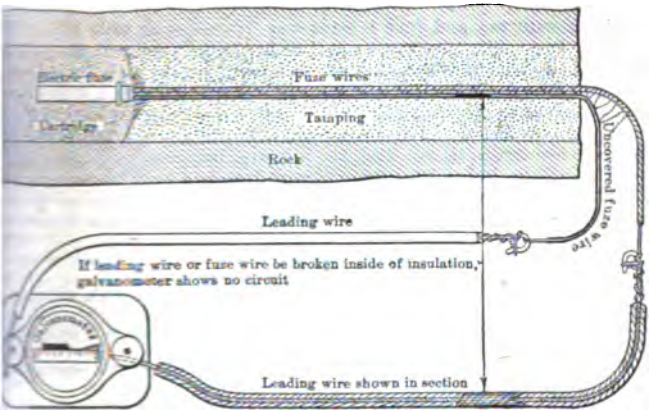
In parallel-series wiring (the caps are first connected in of say from 4 to 10, and each thus connected is in turn at at its two free ends to the l wires. The current requi found by multiplying the nun series by 1.5, which gives the c in amperes. To determine re voltage, multiply resistance of each cap by number of caps in each series, and divid by total number of series. This system is used frequently for firing a large numl charges, where power or lighting current is available.

Electric firing may be done with a blasting machine, or a power or lig current. For firing *with machine*, the caps *must be connected in series*. E

should be scraped bright and clean and twisted tightly together, and if water be present, covered with insulating tape. The two remaining free from the two caps at ends of series are then connected to the leading wires, should be bent or hooked at end, to prevent the smaller wire from slipping



Fuse wires
Tamping
Rock
Leading wire
Uncovered fuse wire
If leading wire or fuse wire be broken inside of insulation, galvanometer shows no circuit
Leading wire shown in section

Fig 15. Poor Contacts in Electric Circuit

wires are subjected to strain. Test circuit with a circuit tester (gal- at ends of leading wires which are to be attached to battery (Fig 15). to be sure there are no broken connections or short circuits. Poor con- connections give abnormally *high resistance* readings. Looped connec-

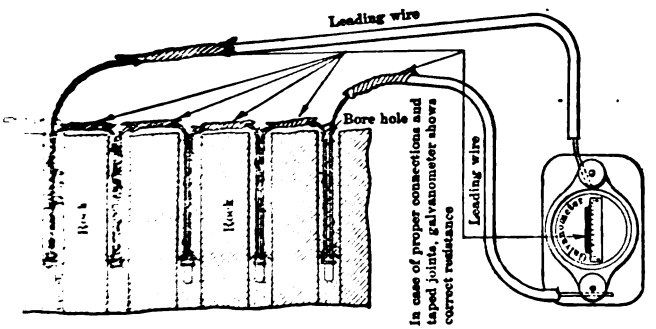


Fig 16. Testing Circuit with Galvanometer

wires may show *no circuit* one moment and *normal resistance* the next. spliced wires touch each other and make a short circuit, *no resistance* is Fig 16). The ends of leading wires are inserted into the binding posts of machine and firmly secured by thumb nuts. Place blasting machine spot (a dry board or plank is best), to prevent its tipping over, and handle with both hands and full force.

If firing is by means of a power or lighting circuit, use a special switch design as to show at a glance whether circuit is open or closed. Avoid cated switches, especially those having springs. The switch should be structed that it can be locked in the open position. The cut-outs on should be of ample capacity.

Firing with cap and fuse is often done by taking an extra piece 2 or 3 ft long, and cutting notches in it with a knife at intervals of abo The end of this fuse is then lighted, and, when powder train burns t notched place, the flame spits out vigorously. By directing each of thes against end of the fuse to be lighted a round of shots may be lighted w tainty, in a few seconds. This method may inflict disagreeable burns on t hands unless care is taken. Lighting fuse with hat lamp or candle is as the spit of the ignited fuse may extinguish flame and leave blaster in th The surest and safest method is to slit the fuse at the end to expose powde and light it with the glowing end of a burning cotton rope, such as windo or clothes line.

Charging

Don't tamp with iron or steel bars. Use only a wooden tamping stick, with n parts.

Don't force a primed cartridge into a drill-hole. Have hole drilled of ample cartridge.

Don't cut or break a dynamite cartridge while frozen, and don't rub a cartridg hands to complete thawing.

Don't prime dynamite cartridges, nor charge nor connect drill-holes for electri during immediate approach or progress of a thunderstorm.

Don't fasten a blasting cap to the fuse with the teeth, nor by flattening it with use a cap crimper.

Don't attempt to use electric blasting caps with ordinary insulation in very we For this purpose secure waterproof caps.

Don't handle fuse carelessly in cold weather; when cold it is stiff and cracks ea

Don't "lace" fuse through dynamite cartridges. This practice is frequently resp for burning the charge.

Don't cut fuse short to save blasting time. It is dangerous economy.

Don't use fuse that has been injured by falling rock or in other manner.

Firing

Don't explode a charge before every one is well beyond danger zone and protect flying débris. Protect supply of explosives also from this source of danger.

Don't explode a charge to chamber a drill-hole and then immediately reload it, hole will be hot and second charge may explode prematurely.

Don't use a "permissible" powder in same drill-hole with another explosive.

Don't hurry in seeking explanation for a misfire.

Don't drill, bore, nor pick out a charge which has failed to explode. Drill and another hole at least 2 ft from the missed one.

Don't expect high explosives to do good work if you try to explode them with a ator weaker than No 6.

9. Special Uses for Explosives

High explosives in coal mining. Use of the "permissible explosive defined by testing station of the Bureau of Mines (19), is increasing in anthracite and bituminous fields. They were used at first in gaseous and mines solely as a safety precaution, because of their comparative freedom liability to ignite gas and dust mixtures. It is now recognized that, by gent use of these explosives, the softest coal is shattered as slightly as with est grades of black powder (23). Permissible explosives are used for rock in hard-coal mines, and in bituminous mines for coking coals, where gas p

encountered. Different kinds of permissible explosives should never be in same hole.

Ore mining. The best type of explosive for a given case can be determined by experience. It depends not only on character of ore, but on ventilation and cost of labor. It is often feasible to substitute with satisfactory results a less expensive explosive for a more costly one, in mines where the miners may be unwilling to adopt methods of drilling, charging, and firing other than those to which they are accustomed. Thus, in soft hematite, a slow-acting ammonia powder properly primed, loaded, and confined, will often break more ore per shift than a more expensive dynamite handled unintelligently. The use of short fuse, lacing fuse through cartridge, and insufficient tamping are dangerous extravagant practices, often difficult to eradicate (18, 20).

Cutting or tunneling. It is desirable to "pull the cut" at the first shot; hence it often pays to use a stronger explosive for firing the cut than is required for the relief, rib, and lifter holes. It is impossible to increase effectiveness of a round by loading the cut-holes by increasing amount of explosive beyond a certain point because a definite amount of tamping is required to prevent charge from blowing out. Generally, cut-holes require an explosive having strength and density of 60% gelatin. Blasting gelatin is sometimes the most economical for this purpose, in spite of its relatively high cost. In refractory rock, or one with irregular stratification, cut-holes are often blasted more satisfactorily by electricity than with cap and fuse. Delay electric caps (Art 10) are advantageous where cut-holes bottom up well; but they should not be used in same round as cut-hole shots, if latter require to be loaded and fired a second time.

Stoping. Every mine is an individual problem. The principal point regarding the explosive is the size to which it is desired to break the material. For coarse, ammonia dynamite breaks fine enough for easy handling without undue shattering. Where ventilation is poor, gelatin or ammonia dynamites are necessary regardless of their other properties, and with much water, gelatin is best. Ammonia dynamite has added advantage that it will "stick" in "uppers." If it is to blast out dry timbers in old stopes, to allow the top to cave and fill the worked-out spaces, a permissible explosive should be used, to avoid possibility of gas.

When firing with cap and fuse, the LEAD (difference in length of fuse in holes intended to fire in succession) should never be less than 10%. For instance, if the last of such a round of holes has a 5-ft fuse, the hole to be fired next should have a fuse at least 6 in longer. With less "lead" than this, variation in burning speed of even the best fuse may cause holes to fire out of order, generally spoiling the shot. When fuses are not lighted in their proper order, the necessity for increased "lead" is apparent. When firing holes in rotation the priming cartridge is sometimes placed at or near bottom of hole, so as to have all fuses lighted at a safe distance inside the holes, when first shot explodes; then, if the fuse in a hole is shot off, its fuse will not be cut, causing misfire. This practice is used with ammonia dynamite or gelatin dynamite, but never with straight nitrates, which are readily ignited by the least side-spit from a fuse and are more liable to burn in the hole. EFFICIENT TAMPING SHOULD BE INSISTED on. It produces greater effect, and the more complete the detonation, the fewer will be the fumes. Ready-made paper tamping bags are a convenience; their use leads miners to exercise more care in tamping.

Tunnel driving. The most satisfactory explosives are the gelatins, which have maximum density and water resistance, and produce minimum of fumes. During the heading, the charge must be concentrated in the bottom of the

holes, to leave room for sufficient tamping to insure a clean break. Th
are usually wet, especially in the bench, and in dry holes or uppers, g
desirable because it can be relied upon to "stick." Ventilation in tu
generally poor and the fumes from gelatins are the least noxious of
explosives. For heading cut-holes, 60 or 75% gelatin or blasting g
generally used; for relief, rib, roof, floor, and bench shots, 40% gelatin is
strong enough. In soft rock, and small tunnels or drifts, a good meth
drill a hole straight into center of face, spring or chamber it once or tw
load for final shot with a fairly large charge of blasting gelatin, well tamp
moist sand.

Quarrying dimension stone, including stone for fills, rip-rapping, and crit
well as for building. Use slow-acting explosives; the more powerful, quick-ac
plosives shatter the stone. Granular, and other slow-acting powders, such as
freezing ammonia grades, may be used in holes where an air space is left for st
line of fracture. For subsequent blasting, black powder is best, fired by electri
ordinary fuse, or electricity. For large charges, blasting powder is fired with ac
by a dynamite primer.

Quarrying small stone (for crushers, cement works, kilns, etc). High e
may be used, the one best adapted to be determined by experience. Quick-ac
plosives are best for rock which readily transmits shock of explosion to a cons
distance. Hard limestone, trap, granite, etc, usually require straight N G dy
of 30% strength and upwards. In very wet holes, where explosive is immersed
hours, gelatin dynamites must be used. In dry work, and in rock which absorl
of shock of explosion, slow-acting explosives, like granular powder and low-
ammonia powders, are usually best. Quick-acting explosives should not be used
like sandstone and marl, nor slow-acting explosives in flint, granite, or the like
freezing explosives of all grades, especially low-freezing gelatins, are preferable
weather, because they do not suffer loss in efficiency as noted with the straight

Stripping. The slowest-acting high explosives are best; granulated dynami
low grades of low freezing ammonia dynamites 20 to 30% being generally us
heavy stripping holes should be sprung and fired with slowest-acting explosiv
dry work, a mixed granulated blasting powder is most economical. For moist
use granulated dynamite. If very wet, a low-grade straight dynamite. High-grad
may be used for stripping charges, but not for final charge
where holes are full of water.

Consequently, in case ... of one of the electric caps or connections, all the holes will be exploded ... In submarine work, holes are generally untamped, except by ... and the quicker-acting straight dynamite therefore does better work. ... cartridges should just fit the holes; especially necessary for shallow holes.

Miscellaneous uses: clearing land of stumps and boulders; ditching and draining ... breaking log and ice jams; destroying wrecks; cutting off pilings; breaking ... tree planting; hardpan and subsoil blasting; digging holes for posts and poles; ... ing for foundations and cellars; trenching for tiling and pipe lines; breaking ... re and other materials; loosening frozen material in railroad cars; tearing down ... ings; splitting logs for railroad ties, fence rails, etc; cutting off large fires; ... snow slides; breaking old building foundations; blasting old mine timbers; ... ing forest fires.

Black blasting powder in coal mining. Black powder has so long been ... coal mining that, as regards execution only, it is considered best for this ... Most coal miners are so familiar with its use, and good miners can judge ... curately, that excellent results are usually obtained with it (15). The slow ... action of black powder produces a large percentage of lump coal. Be- ... of its bulk, it can be charged advantageously and estimated so closely that

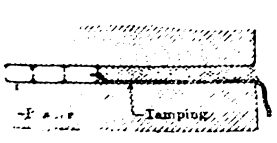

Fig 17. Blasting in Coal with Black Powder and Fuse

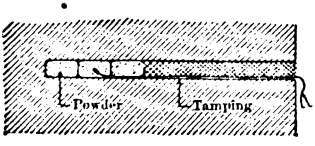

Fig 18. Blasting in Coal with Black Powder Middle Cartridge Primed with Electric Squib

... generally be used more economically than other powders. But, as black ... is loose, considerable care and judgment are required to get best results. ... powder must be made up by the miner in paper cartridges or shells of ... size. In doing this, observe following points:

... cartridge of proper diameter to slip into the hole without too much ... space.

... cartridge of proper length to hold just the quantity of powder necessary.

... the powder down into the shell, to compact it, to minimize air-space ... the full force.

... cartridge is placed in hole it must be well pushed back, unless an air- ... desired to cushion force of explosion.

... electric squib (Fig 17 and 18) is fastened in cartridge to ignite powder,

or a "needle" (Fig 19) or a "blasting barrel" (if hole is wet) is inserted powder, and the tamping compacted firmly around it. The more charge is confined, the greater t developed. When unconfined simply burn (15).

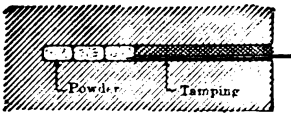

Fig 19. Miner's Needle, for Squib

If a miner's squib (Art 10) pull out needle and insert squi end first, into hole made by need the blasting barrel, and ignite sm of squib. The squib burns for seconds, and then shoots back into the powder, igniting it. Use right tamping, so that needle-hole will be smooth, or, if barrel is used (¼- pipe), see that the hole in it is clear and clean.

When black powder is ignited with squib or fuse, the force seems to through seams of the coal, displacing it forcibly. It does not exert a sharp and therefore does not produce much fines, if proper granulation of powder and correct quantity be used. When very slow action is desired an air-space is left, either between powder and tamping or around cartridge (Fig 20). The proper granulation of black powder is determined only by knowledge of the powder and the coal, and by trial. A test is necessary to determine conclusively which size of grain is best for any particular coal.

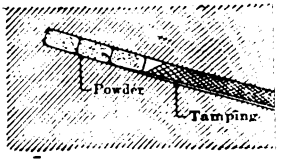

Fig 20. Blasting in Coal. Air S between Charge and Tamping

Earth-work and soft-ore mining. In blasting soft iron ore in op work, holes are drilled by steam drill, or by hand churn drill operated by men. Holes are usually sprung with dynamite and fired with black po Miniature tunnels, gopher holes or coyote holes, as they are sometimes calle used in the stripping operations, and are also fired with black powder underground mining of soft iron ore, the approved method is to fire a c hole, after it has been sprung several times, and then square up with relief a holes. In this method, the lower strengths of low-freezing ammonia dyn are preferred to other explosive. In harder ore the V-cut is used, with ammonia dynamite.

Railroad work. In cutting through fairly solid rock, the holes are usually 18 o deep, spaced 8 ft apart; they are sprung with 50% straight dynamite until each ho hold sufficient explosive to break material small enough to be handled by steam s Roughly, from 25 to 75 lb explosive per hole is used in rock of average hardness it is economical to fire simultaneously as many holes as possible, a large-size bl machine, or a power or lighting circuit, should be used for firing. For soft rock, clay, loam, or sand, it is economical to use a power churn drill. This makes a 4 t hole, of any required depth, usually 40 to 100 ft; holes usually spaced 15 or 20 ft The holes are often sprung with dynamite, and after thorough cooling, usually over are charged with black powder, sometimes several tons in a hole. Black powd granulated dynamites can be used only when holes are dry, and with great care working near steam shovels, locomotives, etc, as many accidents have occurred sparks dropping into black powder. If work is wet and sparks can not be avoided, fairly low-grade low-freezing ammonia dynamite. In firing simultaneously a large ber of holes (50 to 100), use waterproof electric caps, to prevent leakage of current th rock, with attendant chance of misfires.

10. Blasting Supplies

Blasting caps. A cap is a copper cylinder, closed at one end, containing a charge of detonating composition, and is fired by a fuse. Caps are ... according to quantity of detonating composition contained (Table 4).

Table 4. Fulminate of Mercury Blasting Caps

... of charge, grains	15.430	23.150	30.860
" " grams	1.000	1.500	2.000

Note The above tables refer only to caps charged with fulminate of mercury consisting usually of 80% fulminate of mercury and 20% chlorate of potash), ... the standard against which other detonating compounds are graded. Other ... are also used, in charges of such amount that the detonating effect is equal ... of corresponding grade of fulminate composition.

... high explosives, the stronger the cap the better the execution, as a rule. ... detonators should be used for tunneling, shaft-sinking and similar work; ... charges sometimes require No 8. Caps should never be crimped on fuse ... with special crimpers made for purpose; biting them, or nicking them ... knife, is neither efficient nor safe. They should be stored in a dry place, ... nature weakens their force. DO NOT ATTEMPT TO EXTRACT COMPOSITION ... CAP SHELLS; it is exceedingly sensitive and is often detonated if scratched ... out with a pin or similar instrument. Miners should not wear oil or ... hat-lamps when handling caps; many accidents have occurred from ... falling into a box of caps.

Electric blasting caps (fuzes) (Fig 21). An electric cap consists of a ... shell (*A*), 1⅜6 to 2 in long by 0.273 in diameter, closed at one end. It ... a charge of detonating composi- ... *B*, in which is embedded a fine plati- ... wire (*E*) connecting the two copper ... (*D*). Wires (*D*) are held in place and ... insulated from each other by a composition ... or plug (*F*), which, in turn, is retained ... composition (*G*) held by corrugations in shell. Electric caps are used for ... in gaseous and dusty collieries, and for firing charges simultaneously, thus ... ensuring explosive. ONLY ONE KIND OR BRAND OF ELECTRIC CAPS SHOULD BE ... FIRED IN ONE SERIES. Different brands vary in sensitiveness, and if the ... in a series are not uniform, the least sensitive will probably misfire.

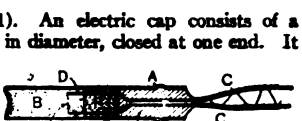

Fig 21. Electric Blasting Cap

Delay electric blasting caps are for firing blasts in 2 or 3 volleys application of electric current. They are used with a special detonator, "No Delay," which is necessary because first and second-period dela caps are less sensitive to ignition from passage of electric current, and can not be used in series with ordinary electric caps. When current mitted, about one second elapses before first-delay caps detonate, a period between these and second-delay. These detonators are useful i driving and are especial mended for shaft-sinki enabling blaster to fi round without returnin

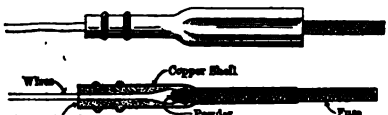

Fig 22. Electric Fuse Igniter

Electric fuse ignit 22) are devices for ig fuse, usually of high-gra proof quality, by electric

When shipped they are not attached to fuses, but are crimped on wh The interval between the operation of blasting machine (or turning on rent) and the firing of the cap, depends on length of the fuse attached.

Special electric blasting caps. For very wet work, and where sludge a possess high conductivity, special insulation of cap wires is necessary to preven leaking from wires at one end of series to wires at other end, thus forming a shur wires at middle of circuit. This condition can be detected by making resistance of firing circuit on a direct-reading ohm-meter. If reading is the same, there is age; if there is a drop in resistance, after loading in wet holes, there is liability c leakage, indicating necessity for special waterproof cap wires. For firing cl deep water, a special, highly waterproof electric cap is made. There are oth fications for various purposes, such as having wires of larger gage than ord decrease resistance in deep-hole blasting. Electric caps are also made with ir used where only 2 or 3 shots are fired simultaneously. These have much higher resistance than caps with copper wires, and are not recommended for lengths o Electric caps with tin-coated copper wires are used in certain mines where it is ol able to have particles of bare copper in material mined, and where number of fired simultaneously makes use of iron wires impracticable.

Electric squibs (Fig 23) are somewhat similar to electric caps, exce the shell is of heavy paper instead of copper, and cap filling is fine-graine powder instead of a detonating compound. They are especially designed for black powder; can not be used for high explosives. They possess advantage of simultaneously firing several charges, and of permitting more perfect confinement of charge than with ordinary powder squibs; also, the charge can be ignited in middle, giving a little quicker and stronger action and ir explosion of entire charge before any portion can be cut off by a fall of sur ing material. Electric squibs are safer than fuse or ordinary miners' squi cause shots are not fired until every one, including blaster, is at a safe di and hang-fires are entirely prevented. They should always be stored place, being readily affected by moisture. Electric squibs are made witl iron and copper wires, those with iron wire being less expensive but req stronger current (see preceding paragraph).

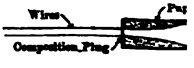

Fig 23. Electric Sc

Miners' squibs are for firing black powder only. The squib consists of a core of p composition tightly rolled in paper; one end terminates in a slow match, made by d twisted end of paper in melted sulphur or other combustible. In using, the squib in mouth of hole formed by withdrawal of needle, or in the blasting barrel (Art 9). other end of hole so formed terminates in the charge. Outer end of squib is lighte

several seconds until its powder core is ignited, whereupon it shoots down into the and ignites that. Time between lighting of fuse and firing of charge can be varied to some extent by position of tail of squib: when turned up it burns more slowly; turned down, much faster. The squib is very cheap, but not so safe as ordinary since it requires an opening through which to travel, the charge is not confined so as with fuse or electric squib.

Safety fuse consists of a train or core of a special kind of powder, tightly wrapped in successive turns of hemp, jute, or cotton yarn, and tape, made more or less waterproof by addition of asphalt or other varnish, or gutta-percha. Usually made to burn, when unconfined, at rate of about 2 ft per min. when tightly tamped, so that gases from burning powder train can not escape, the pressure causes fuse to burn faster. For dry work, hemp fuse is good for powder, but is too small in diameter properly to fit standard caps. The cheaper grades are usually the least waterproof; the more expensive, the better to resist water. For very wet work, or under water, gutta-percha fuse will serve. When extra precautions are necessary, the end of fuse and the cap may be dipped into asphalt paint and dried, or joint between cap and fuse covered with tallow or soft soap. Do not use oil or grease, which is likely to affect powder train by dissolving asphalt varnish. As the powder in a fuse absorbs moisture, always cut off an inch or two from end, before putting in cap. Cut off end square across, push into cap without twisting until fuse touches the cap charge. If fuse is cut at an angle, pointed end may bend over and by covering end of powder train, cause misfire. Nearly every kind of fuse spits out of sides more or less in burning, and therefore should not be placed in the dynamite. When necessary to have priming cartridge at bottom of hole, a fuse should be selected that will spit from the sides as little as possible, as cartridge shells must not be slit; fuse is less likely to ignite dynamite through paper wrapper.

Blasting machines. The usual form is a small dynamo (Fig 24), the armature of which is rotated by a rack-bar and pinion. There are two types, in which rack-

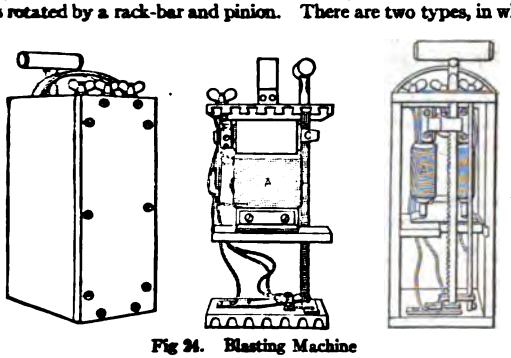

Fig 24. Blasting Machine

bar is either pushed down or pulled up, the dynamo being same in both; the push-down machine is preferred. The current generated during descent of rack-bar is short-circuited through field magnets until end of stroke; then the end of rack-bar strikes spring of circuit breaker, and shunts current through binding posts to external circuit or firing line. Place machine in a firm, level position, and operate with both hands and full force; an attempt to operate it with one hand, or in a half-hearted way, will often result in misfires from in-

sufficient current. Keep blasting machines in dry, cool place. The c
tor, brushes, and circuit-breaking contact points should be kept clear
and free from oil. Oil bearings and gears occasionally.

Circuit testers (galvanometers) are of two general types: one merely
whether circuit is open or closed; the other is essentially a small direct-rea
meter, indicating by movement of a needle across graduated scale the approxim
ance of blasting circuit in ohms. With the latter, it may be determined wheth
blasting circuit is complete, or broken, or short-circuited. By a table, giv
showing resistance of electric caps with different lengths and sizes of connecting
ing wire, the exact condition of blasting circuit at moment of firing may be d
fairly accurately. The circuit-tester is a valuable adjunct, and, where a co
amount of electric blasting is done, should form part of blaster's equipment. I
to breaks and short circuits, it also detects leakage of current through ground,
pipes, steam pipes, and imperfect connections. The instrument is furnished wi
chloride cell, which is constant in its current output. The current thereby gene
weak that the danger of firing an electric cap while testing is remote; but, as a
precaution, tests should be made from a safe distance. The ordinary type
reading ohm-meter and battery tester, containing carbon-zinc dry-cell ba
liable to send sufficient current through a blasting circuit to explode an electric
greater caution is therefore necessary in using them, especially for testing one
time.

Blasting machine testers (rheostats). These are for determining inexpens
capacity and condition of a blasting machine. There are several types. One p
means of sending a current through different resistances and a small lamp, so th
connected to the poles corresponding to type of blasting machine tested, a bri
indicates that machine is up to standard. Another tester has 6 posts, with
resistances so arranged that 20 combinations of varying resistance may be ob
connection with use of an electric blasting cap in series, acting as an indicato
thus possible to determine whether blasting machine is up to strength, and if
how many caps in circuit it is capable of firing. By its use overloading a given
machine is avoided, with consequent danger of insufficient current and misfires.

Connecting and leading wire. Connecting wire is used for connect
electric cap wires of one hole to wires of cap in an adjacent hole. As
dealers in blasting supplies, it is usually No 20 or No 21 B & S gage, wo
1 and 2-lb spools. The use of the larger gage wire is advisable, as it ad
to the resistance of firing circuit. This wire should not be used for con
a line of holes to blasting machine; for that purpose LEADING WIRE sho
used, of No 14 gage or larger. No 14 B & S gage wire, in coils of 50
satisfactory for all kinds of dry work.

Resistance tables. The resistance of copper wire, B & S gage, per 1 000 ft,
usually employed in electric blasting, is:

Gage No	Ohms	
8	0 6271	Power and lighting circuit
10	0 9972	
12	1 586	
14	2 521	Leading wire
16	4 009	Sometimes used for leading wire, but not recommended for firing large circuits
18	6 374	
20	10 14	Connecting wire
21	12 78	
22	16 12	Size attached to electric caps

Wires of electric caps have a resistance of 0.032 ohm per ft (doubled).
platinum bridge of each electric cap has a resistance of 0 859 ohm. Th
distance of iron wire, of size used for iron-wire electric caps, is about 101.0
per 1 000 ft.

Table 5. Resistances of Electric Blasting Caps with their Wires

Length of wire, feet	*Resistance of cap with copper wires, ohms	Resistance of cap with iron wires, ohms	*Length of wire, feet	*Resistance of cap with copper wires, ohms
4	0.987	1.661	20	1.499
5	.....	1.861	22	1.563

Note. — Numbers in parentheses refer to Bibliography at end of this section.

This section contains data on blasting in general, and surface excavation of rock, as ... mining, quarrying, railroad and highway through-cuts, and side-hill cuts, and ... Related subjects are: Tunneling (Sec 6), Shaft Sinking (Sec 7), Machine ... and Compressors (Sec 15) and Explosives (Sec 4).

1. Cost as Affected by Character and Formation of Rock

Rate of drilling is influenced chiefly by the hardness of rock. In general, ... speed in hard rocks is much lower than in soft, though, in some shales ... other friable rocks, the accumulation of sludge in the hole prevents the ... from striking an effective blow, and retards drilling. This is remedied by ... a water-jet (Art 2). In some soft rocks a heavy blow will drive in the ... that it sticks. Seamy, blocky rock also causes sticking or FITCHERING; ... overcome by withdrawing the bit and dropping a handful of quartz ... cast-iron fragments into the hole. TOUGHNESS AND HARDNESS of the rock ... determine in great measure the kind and amount of explosive required. ... cohesive rocks require more powerful explosives and in greater quantities ... soft, brittle rocks. DIP OR SLOPE of the rock strata and presence or absence ... seams also affect cost of excavation. Rock strata may lie at such an angle, ... seams be so located, that the amount of drilling and explosive required is greatly lessened. On the other hand, these conditions may require the excavation of rock outside the desired cross-section.

Overbreakage for 8 months during 1909 in open-cut work on the Livingstone i ment of the Detroit River was 14.7%; 273 750 cu yd of limestone excavation v for, and 314 000 cu yd loosened (11). Overbreakage in open cuts (mostly in g on Grand Trunk Pacific R R, was 10 to 40% (20). Overbreakage in the approac tunnel near Peekskill was 10%, the strata dipping at a high angle (20).

Size into which rock breaks when blasted determines method dling, and influences cost.

Voids in hard rock, when broken by a crusher, amount to about 35% if all s mixed and the stone slightly shaken, but, if screened, each size has 45 to 48% Soft, friable rocks, as shales, break into widely varying sizes and therefore have percentage of voids. Hard rock blasted in large pieces and thrown into cars ha 40 to 45% voids, 1 cu yd of solid rock making 1.67 to 1.82 cu yd broken.

Voids.....	30%	35%	40%	45%	50%
No of cu yd, loose measure, from 1 cu yd of solid rock	1.43	1.54	1.60	1.90	2.00

Swelling in fill. On excavating a mixture of solid and loose rock and earth, in place makes about 1.4 cu yd in fill. If rock be first stripped of earth, and then and dumped by itself, the percentage of voids is larger. At Boulder, Colo, 3 60 of solid rock made a 5 340 cu yd embankment; a ratio of 1: 1.51. In Virginia, cu yd of limestone and mica schist, broken and put in embankment, made 90 000 an increase of 80%. In subaqueous excavation, Ashtabula Harbor, O, 62 869 (place measure) gave 103 537 cu yd measured in scows, an increase of 65%.

2. Drill Steel

Octagon steel is most used. Length of CUTTING EDGE (gage) of bit from 200% of width of shank for soft rock, to say 130% for hard; chise is generally used for hand drilling, and cross, X, Z, and other shapes for m drills. The projecting ends of cutting edge are the WINGS.

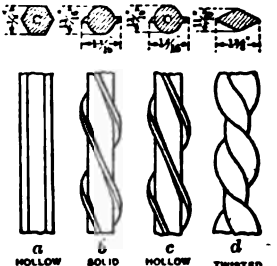

Fig 1. Special Drill Steels

Hand-drilling bits. Steel is usually ¾ to ... For soft rock, ⅝-in steel may have a 1-in ... in steel, a 1.25-in bit. Diam of the "fin-... or last bit of a set for a given hole should ... less than 0.75 in for charging dyna-... For black powder, the hole must be much ...

...el edge of a hand bit is usually convex; its faces should be at 90° for hard rock, ...° to 45° for soft; in sandstone a blunt-edge cuts faster. GAGE of bit decreases as ... shank, or depth of hole, increases. The reduction in gage depends on hardness of the rock. In soft rock, the bit wings wear slowly, and the decrease in gage is less than for hard rock. Reduction in gage is commonly 1/32 to ⅛ in per bit.

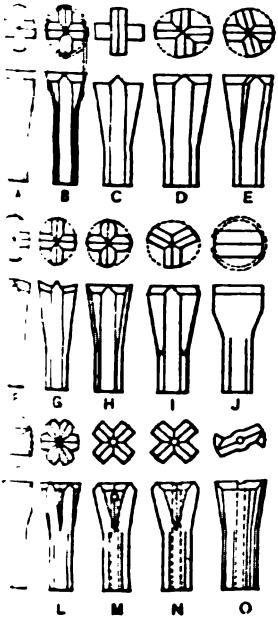

Fig 2. Shapes of Machine-drill Bits

Machine-drill bits. Fig 2 shows different shapes (T. H. Proske, *M & S Press*).

A, standard American cross-bit. *B* has an excess clearance angle (16°) and round edges (see *A*); wears rapidly on the corners, and hole tends to "rifle" (see below). *A* is stronger than *B*, and in soft rocks will remain sharp about 4 times as long. *C*, Simmons bit: 2 wings are solely for reaming and keeping the hole round; a rapid driller in hard rock. *D*, Brunton bit, which combines the easy-sharpening qualities of the cross-bit with advantages of the X. *E* is the X-bit, the wings of which must revolve 180° for the edges to strike twice in same place; this prevents RIFLING. *F* is a high-center bit, favored for hammer-drills, because it starts a hole easily; but it is apt to follow seams and cause crooked holes, and does not MUD (clear out the cuttings) freely. *G* is a fast-cutting bit, but corners dull rapidly and break easily. *H*, round-edge bit, is good in soft rock, but rifles in hard... *I*, Y-bit, muds freely as there is plenty of room for the cuttings to escape; difficult to sharpen by hand. *J*, bull or chisel-bit, formerly used for hard rock in Missouri and still sometimes used in marble quarrying; has been superseded by power-sharpened X-bit; cuts fast in seamy shale with a water jet. *K*, Z-bit, sometimes employed where hand sharpening is in use. *L*, 6-wing rosette, made with power sharpener and used ...mer-drills only. *M*, cross-bit, for hammer-drills. *N* is the same bit, with hole at ...stead of at the side. *O* is a Z-bit widely used in Germany, usually with a ...ted shank.

Table 2. Shapes and Drilling Speeds of Hammer-drill Bits (Sullivan M

Description of bit	Duration of run, min	Diam of hole, in	Aver in drilled per run, 70 lb air press	Aver in drilled per run, 85 lb air press	Remarks
25° diamond-point +	2	1⅝	6⅝	8½	Spots easily. Hole rifles Rotation easy. Gage hc
25° diamond-point ×	2	1⅝	6	7¾	Spots easily. Drills round h tation easy. Gage fairly
Convex +	2	1⅝	6¼	8¼	Spots easily. Hole rifles Rotation easy. Gage hc
Flat +	2	1⅝	6	7½	Difficult to spot hole. Hc
4° concave +	2	1⅝	5¾	8¼	badly. Rotation hard. fairly durable.
25° pointed Bull −	2	1⅝	5¾	7	Spots easily. Drills round h tation easy. Gage wears
Flat Bull −	2	1⅝	5 15/16	7¼	Difficult to spot hole. Hc badly (3 flutes). Rotati Gage wears rapidly.

Special bits for removing cuttings. A spiral steel (like a wood propels the cuttings from the hole. Cruciform steel, with lugs at inte the angles, performs a like function, when used on reciprocating drills, acting as scrapers in removing the sludge. A steel with a longitudina ber from the bit's point to a side outlet close to the chuck, also keep clear. A portion of sludge enters the chamber on the down stroke and is out by the entrance of more at each succeeding stroke. Locher tracti has large steels, with a hollow chamber and ball valve. COMPRESSED WATER forced through hollow bits aids in removing cuttings; air alone rocks makes much dust (Sec 15, Art 25; Sec 23, Art 5). Water allay and preserves temper of the bit. WATER-JET is effective. A small pip serted in the hole alongside of the bit, and a stream of water forced thr

Quantity of water for jet (20): Let Q = gal of water per min; D = diam of of drill hole, in; D' = diam of drill steel, in; d = diam of largest grain of slu Then, $Q = 7\,(D^2 - D'^2)\,\sqrt{d}$; or, neglecting area of steel, $Q = 7\,D^2\,\sqrt{d}$. Vel the rising current must exceed that at which the particles would fall in still water. chips 1.4-in diam (as in shale), require 22 gal water per min in a 2.5-in hole. quartzite, with drills operating at 60 to 65 lb air press, dry holes were drilled at per min cutting time, while holes with a water-jet under a press of 40 to 80 lb p were drilled at 0.78 to 1.34 in per min.

Drill steel sharpening is done by hand or by machine sharpeners. rocks, a bit must generally be sharpened for every 4 ft of hole; in medium for every 2 ft; in very hard rocks, for every 1.5 ft. A blacksmith and help sharpen about 140 bits per day at a cost of about 4¢ per bit. A machi sharpen up to 60 bits per hr, or say 200 to 400 bits per day. Machine-sha bits cost about 3¢, last longer, and cut better than hand-sharpened bits.

Heating. Drill steel contains 0.8 to 1% carbon; by overheating, steel is BURN becomes softer through loss of C. For sharpening, heating must not be contin long, nor carried above a cherry red. The bit and part of the shank are well be the fuel, which should be charcoal, coke, or blacksmith's coal. If the fuel contains s the steel becomes brittle when hot, or HOT SHORT; if it contains phosphorus the brittle when cold, or COLD SHORT. Oil and electric furnaces are sometimes used, gives too large a flame and electricity requires a special forge.

Bit sharpening. Bits should be constantly turned in the fire, removed ... red and dressed. The edge of a badly-worn chisel bit is first upset ... proper width. The bit is then held on the anvil at a slope of about 1 ... on, with its edge even with edge of the anvil. While hammering ... ed after each half-dozen blows. A file may be used on the hot bit for ... ing. Blows should be light and glancing, to draw the fibers of the ... arts the edge, thus toughening the metal. There are 2 methods of ... g machine-drill bits: SET-HAMMER and FULLER-AND-DOLLY. In the ... et-hammer is placed on the bevels for driving the steel back. After ... sharpened a few times a drill bit must be reformed. In the second method ... el is first drawn sharp at the corners with a fuller and then set back in ... ter with a dolly.

Machine sharpening. Power sharpeners are made by Word Bros, Ingersoll-... Co, Hardsog Drill Co, Fairbanks-Morse Co, and a number of others. ... sist essentially of 2 air-driven hammers for shaping the bit; one hori-... the other vertical. Price is from $800 to $1 200.

Tempering. After being sharpened, the bit is re-... for tempering. When cherry red it is plunged ... water for a moment to cool it partially, and then ... on a stone, or sanded board, to remove scale. ... heat advances again toward the tip, the play of ... colors should be watched in a dark corner of the ... The colors appear in following order: Pale yel-... (430° F.), straw (470°), brown (490°), purple (530°), ... blue (560°). If they do not advance parallel to the ... edge, that side on which the colors are advancing ... rapidly should be held in water. When the edge ... straw color plunge the bit into water, wave it back ... forth to insure rapid and even cooling, until steam ... to form, and then leave it in the quenching bath. ... may be of water, salt and water, rape-seed oil, tallow, or coal-tar; brine ... the drill fastest, coal-tar slowest. Fig 3 shows a bath in which a grate, set ... in below the water surface, supports the bits at the proper depth.

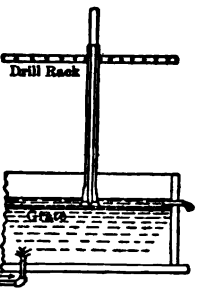

Fig 3. Drill-tempering Tank

3. Methods and Cost of Hand Drilling

Methods. SINGLE-HAND DRILLING is usually economical in the softer rocks ... depth of about 3 ft; wt of hammer, 3.5 to 4.5 lb. DOUBLE-HAND drilling is ... for deep holes or very hard rock; 2 strikers may be employed; wt of ham-... 10 lb. For 6 to 8-ft holes, the starting bit is usually 1.25 to 1.5-in gage. ... DRILL, well handled, is effective for deep vertical holes. It is raised and ... ped by one or more men.

Effect of diam of hole on the speed of drilling has never been fully deter-... ed. In general, doubling the diam divides the speed by from 2 to 4.

Direction of hole. A horiz hole is drilled at about 0.5 the speed of a verti-... down hole; in "uppers" the speed is materially less. Horiz and up holes ... usually dry, and the cuttings prevent the bit from striking the rock effec-... water poured into a down hole keeps the cuttings in suspension, per-...ng the bit to strike against a relatively clean face.

Hardness of rock as affecting speed of drilling. In vertical holes (1.5-in ... ing bit) 1 man holding and 2 men striking can in 10 hr drill 6-ft holes at ... ing rates: granite, 7 ft; trap, 11 ft; limestone, 16 ft.

Table 3. Cost of Hand-hammer Drilling (Original)

(*a*) Including 3.5¢ for "nippers" (carrying drills) and 5¢ for blacksmithing. usual depth for hammer drilling; churn drilling cheaper. After reaching dep ft all 3 men used hammers, the drill turning of itself on the rebound. (*c*) Inclu for sharpening. Machine drilling cost 14¢. (*d*) Steam-drill work cost 18.8¢ pe this work, due to sticking of drills. (*e*) Machine drilling, including sharpening o cost 39¢. (*f*) Including 9¢ for sharpening steel.

Cost of hand churn drilling. 30-ft holes, 2.75 in diam at start and 1.5 in at f in blue sandstone, cost 35¢ per ft. In 10 hr, 3 men put down the first 18 ft and 4 n last 12 ft. In brown sandstone, cost was from 35 to 40¢ (labor, 15¢ per hr). In and sandstones of the coal measures, holes 20 to 24 ft deep cost 40¢ per ft. In the Range, Minn (Art 10), 4 men can drill 40 ft of 1.5-in hole in 10 hr in stripping overb and 96 ft in iron ore. With wages at $2, cost in stripping is 20¢ per ft; in ore,

Hand-power auger drills are sometimes used for prospecting and l blast holes in soft ground, as coal, slate, shale, salt, gypsum, and talc. vary from simple hand augers to elaborate machines with tripod or post m ings. Mounted machines weigh 80 to 100 lb; cost, $30 to $70.

4. Methods and Cost of Open-cut Machine Drilling

Drill mountings for open-cut work are the tripod (Sec 15, Art 29), quarry-bar, g and special carriage for deep holes (Fig 4). QUARRY BAR is a horiz bar supported a end by legs. It is 3 to 6 in diam, 8 to 12 ft long. Cost, about $160; wt, without dril to 1 500 lb. These bars are primarily for drilling in quarries a number of rows of ve holes close together, but may be used for similar work in trenches, etc. GADDER is a q device for drilling a number of parallel holes in a plane at any angle, from horiz to ver as the undercutting holes in a bench partly freed by channeling. A heavy carriage, ru on a track, has hinged to it a standard, adjustable at different angles, on which sli saddle carrying the drill. Cost of gadder frame, $400 to $450; wt, 2 500 to 3 500 lb,

trucks are used to some extent for deep-hole drilling, and for trench etc. Fig 4 shows a truck carrying a derrick and heavy drill similar to subaqueous drill-boat equipment. It is operated from a central compressed-air or steam plant, or may carry its own boiler. The drill may be stationary, or, as shown, mounted on a turntable. The cuttings are removed from the hole by a water jet or by special steels (Art 2). There are other devices for mounting one or more ordinary machine drills on a bar. The electric-air drill (Sec 15) is also furnished on a carriage. A special device for sewer work is described in Art 11. Respecting drill carriages, see also Sec 6, 15 (10, 20).

Cost of machine drilling comprises: (*a*) wages of drill crew; (*b*) proportion of wages of power-plant crew; (*c*) fuel; (*d*) drill sharpening; (*e*) repairs and renewals; (*f*) oil and water; (*g*) interest on plant; (*h*) depreciation of plant; (*i*) proportion of general expense including taxes, and (*j*) setting up, dismantling, and moving plant.

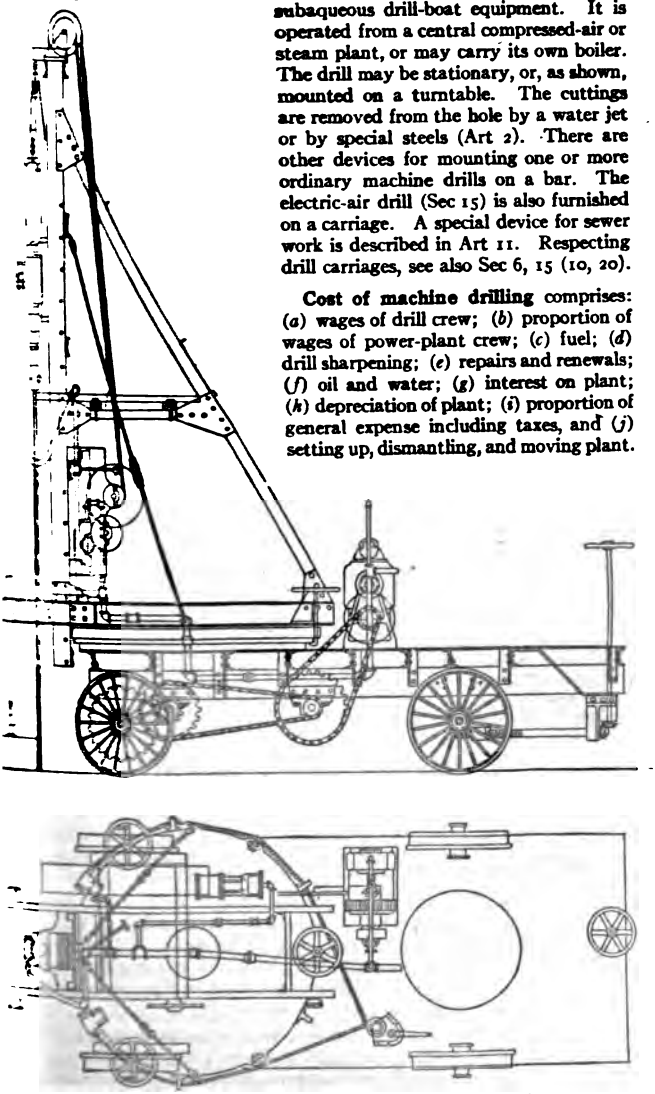

Fig 4. Ingersoll-Rand Deep-hole Drill Wagon (15-ft Turntable)

Factors affecting speed of drilling: (*a*) character of rock, as hardness, seams, sludge, and dust-forming qualities; (*b*) time for changing bits; for taking down, moving, and setting up machine; (*d*) depth of hole; (*e*) d of hole; (*f*) diam of hole; (*g*) use of air or water, or both, in the hole; (*h* of bit; (*i*) quality of blacksmithing; (*j*) percentage of time lost, as by b breakdowns, delays, etc; (*k*) size, weight, and type of drill and mounting or steam press at the drill; (*m*) the energy and skill of crew.

Time occupied by the different operations in drilling may be classed un TING TIME and DELAYS, the sum of which gives total CYCLE TIME for drilling Delays comprise time to (*a*) raise drill, (*b*) loosen bit, (*c*) remove bit, (*d*) get bail, (*e*) get bit, (*f*) insert bit in chuck, (*g*) tighten chuck, and (*h*) get started. the cycle time, there is the time required to move the drill to other holes, set it up, and miscellaneous delays. For time studies on different pieces of work, see (11 drills were mounted on tripods for holes 7 to 24 ft deep and 2.5 to 5.5 in start, in granite, limestone, and slate. From these records, cutting time average of cycle time; cycle time, 74.7% of total time; time for moving and starting 12.5% of total time; time lost in delays, 12.8% of total time. Cutting speed: in 0.18 ft per min; limestone, 0.13 ft per min; slate, 0.17 ft per min. My own recor 4 to 16 min to drill 2 ft (cutting speed 0.125 to 0.5 ft per min), 2 to 10 min to bits and pump out hole, and 7 to 60 min to set up the drill (20).

Table 4. Average Time Drilling Vertical Holes (Tripod Drill) (Origi

[illegible] drill and hose	0.75	Repairs to drill and hose	0.75
	$11.10		$7.30

[illegible]est, depreciation and general expense are not included. * Machine sharpening.

Hammer vs reciprocating drills (Sec 15). Hammer drills will not stand [illegible]d usage as reciprocating drills; their parts are lighter; the piston and [illegible]cks are subject to crystallization due to the rapidity of the blows; the [illegible] steel often used is high-priced and is more difficult to sharpen. As the [illegible]t of feed of hammer drills is generally shorter than that of reciprocating [illegible], the steels must be changed oftener; but time required for changing is [illegible]. Sharpening hollow steel costs somewhat more. The short feed in- [illegible] danger of the piston cracking the cylinder head, especially when han- [illegible]g an inexperienced man. Hammer drills, while faster in horiz or "dry" [illegible] are slower than reciprocating drills in "down" holes, so common in [illegible]ct work. But, for block-holing, plug-and-feather holes, or holes in trenches or other restricted places, the hammer drill is light and easy to [illegible] and many models require no mounting; it is therefore a valuable ad- [illegible] the heavier machines. It is especially useful for stoping in mines.

Hammer drills. Speed of cutting. A Sullivan, Class D–19 drill, 1.25-in [illegible]er. hollow steel, and air at 100 lb, drilled in granite 1.25-in holes, 1 ft [illegible] an aver of 1.75 min, using 25 cu ft free air per min. A Class D–15 [illegible] same granite, drilled ⅝-in holes at rate of 1 4½-in hole in 10 sec, and a [illegible] hole in 15 sec. In trench work in oölitic limestone, 12 DB–15 drills [illegible]d 90 1.5-ft holes per drill per 10-hr shift for 12 mo work. Best record [illegible] 1.5-ft holes in 10 hr and 36 3.5-ft holes in 7 hr. In dark green granite, [illegible] drill in 16 hr made 47 ft in 25 holes, from 19 to 36 in deep; a DB–19 [illegible]de 19 ft in 5 holes, from 32 to 60 in deep. A DC–19 drill, in soft sand- [illegible] made 20 holes 18 in deep, at rate of 25 sec per hole.

Electric drills. Advantages, as compared with air drills: low first cost of [illegible] ease of installation; economy of power. Disadvantages: very high [illegible]d maintenance; loss of time due to breakdowns. Electric drills have been successful and are little used (See Sec 16) (10, 20).

Air-electric drills (Sec 15) are driven from a self-contained compressor oper- [illegible] an electric motor.

Performance of electric drills (11, 20). 8 Marvin solenoid drills, oper- [illegible]ht and day for 2 yr in hard, seamy limestone, made 25 ft in 10 hr, as [illegible]ed with 45 ft by air drills. They had small pulling power after striking [illegible] and the steel stuck repeatedly. 2 Adams electric drills were tested in [illegible] diabase during 53 consecutive 10-hr shifts, with 2 2.75-in air drills. The [illegible]eraged 4 ft per hr during 317 drilling hr, with no stoppage for repairs; [illegible]tric drills averaged 2.55 ft per hr during 100 drilling hr, with 17 hr lost [illegible]rs. 4 Gardner No 15 drills, used for 2 yr in firm augite-diorite and [illegible]rite, averaged 13 holes, 8 ft deep, per drill per 10 hr. Cost of drill and sharpening (not including overhead expense) was 10¢ per ft of hole. From

2 to 7 Siemans-Halske drills were successfully used in German iron mi
fissured, sticky ground, in U S, this drill has been a failure. Dulles
drill, tested in trap and granitoid gneiss on the Catskill tunnels, made
of 5.3 ft per hr per drill for 5 weeks. Fort Wayne drill, tested in t
place proved strong, but lacked power to cut hard rock. 3 Box drills
Mexico for mining in metamorphosed lime shale, pyroxene, and quartz,
4-ft holes in 24 to 28 hr per drill. Cost of repairs was very high, b
drilling with inefficient labor cost 37 to 50¢ (Mex) per ft and was more ex

Cable, well, or churn drills (Sec 9) are extensively used for deep h
blasting in the softer rocks. Advantages, as compared with machin
Any depth can be drilled, to the possible limit of blasting; no strippin
overlying earth is necessary; holes in high faces are drilled to full depth,
of working in benches; the large-diam holes hold larger charges, hence wid
ing of fewer holes, and consequent saving of time; smaller consumption of
power. To offset these points, machine drills possess the advantages of p
ity and speed of drilling, which make them generally preferable (Sec 15

Size of churn-drill holes. In sandstone, 3-in bits are common,
6-in holes cost little more, they are economical where large, concentrated
are required. In a 16-ft quarry breast, with a 6-ft bottom stratum a
upper strata, 4-in holes were spaced 9 ft apart and 10 ft back. Thoug
was charged with 33 lb of 33% dynamite to within 20 in of the top, and
tamped with clay, the rock broke poorly. 5¾-in holes, spaced 12 by 12
charged with 42 lb of dynamite each, permitted 39 in of tamping, and
well. With 4-in holes, 1 ft of hole broke 8 tons of rock (1 lb dynamite
tons); with 5¾-in holes, 1 ft broke 12 tons of rock (1 lb dynamite to 4.5?

Runner, $3; helper, ...reman, $2; water, 75¢; coal, $1; total, $8.25; cost per ft, 11.8¢. The larger ...e churn-drill holes saved dynamite, as each hole was sprung but 3 times, whereas ...chine-drill holes had to be sprung 4 or 5 times.

...osts of churn drilling for blasting (20) (see Sec 9, Art 8).

5. Theory of Blasting

...ctors influencing results of blasting: size and number of free faces; cohesive ... of the rock; structure of rock (massive, jointed, laminated, stratified, or fissured); ... and nature of the explosive; character of fuse and tamping; whether the shot ... or simultaneously with others; whether the broken rock falls or must be ... the blast; form and size of chamber containing the explosive; proportion of ... of line of least resistance to length of the hole, and to height of free face (3, 10, 20).

...les for blasting. Many have been formulated, but all neglect some of the ... stated above. Also, most published rules are applicable to black powder ... are valueless for high explosives; and practically all ignore the use to which ... rock is to be put. Hence, experience and judgment are more useful in de... proper methods than the theories and rules summarized below. Theory of ... is discussed in detail in (5). According to the CRATER THEORY, a charge in a ... of earth or rock with horiz surface will blow out a funnel-shaped crater, the sides of ... have a slope of 1 to 1 to the FREE FACE (Fig 5). Distance *DB* (more exactly, *DF*) ... LINE OF LEAST RESISTANCE = l; hence, volume of crater ... $l \times w^2 = l^3$ (nearly). Hence, general formula for ... of rock loosened is $V = ml^3$. According to Schoen (5), ... for tough, soft rock, and 0.9 for hard, brittle rock.

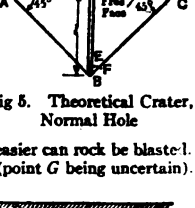

Fig 5. Theoretical Crater, Normal Hole

...rection of hole. If vertical (normal, as in Fig 5), the ... may blow out tamping and fail to break; hence, hole ... be inclined (Fig 6), to reduce chances of a blow-out, as ... to increase area of free face and volume of rock broken. ... inclination of drill hole is 45°.

...ect of free faces. The greater the area of free face, the easier can rock be blasted. ...ows area of volume broken when there are 2 free faces (point *G* being uncertain).

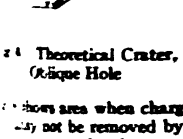

Fig 6. Theoretical Crater, Oblique Hole

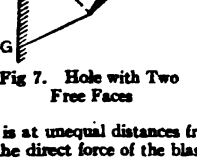

Fig 7. Hole with Two Free Faces

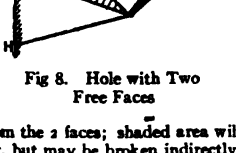

Fig 8. Hole with Two Free Faces

... shown area when charge is at unequal distances from the 2 faces; shaded area will ... not be removed by the direct force of the blast, but may be broken indirectly. ... 3 or more free faces are exposed, the longest line of resistance should not exceed 1.5 *l*. ... the aid of gravity, *l* should be horiz, and the longest line of resistance vertical.

Relation of factors. l should be proportioned to size and diam of the hole. eral, in open-cut work the depth of holes should be 1.5 l.

Table 7. Relations of Diam & Depth of Hole, & Length of Line of Least Re

Diam of hole, in	Depth of hole, ft	l, ft	Diam of hole, in	Depth of hole, ft	l
1.25	3.50	3.50	1.5	12.00	6
1.25	5.75	3.75	1.75	5.00	5
1.25	10.00	5.00	1.75	9.00	6
1.5	4.00	4 00	1.75	14.00	7
1.5	7.50	5.00			

Holes blasted simultaneously. Fig 9 shows the effect. If a and b are blas arately, c would not break out; when blasted together c is broken, if x is not to In ever hard rock, $x = 1.5\,l$ to $2\,l$; in weak rock, be about equal to l.

Fig 9. Effect of Holes Fired Simultaneously

Rock coefficient. To obtain it, select a homo bench 2 ft wide by 3 ft high. In this drill seve tical holes, so spaced that the blasting of one crack nor start the rock around another. Char with different weighed amounts of the explosiv used, beginning with a small quantity. Fire the holes separately. If C = roc P = wt of powder, lb, l = line of least resistance, ft; then $C = P \div P$, and P For 3 free faces, use 0.66 P; for 4 faces, 0.5 P; for 5, 0.4 P; for 6, 0.25 P.

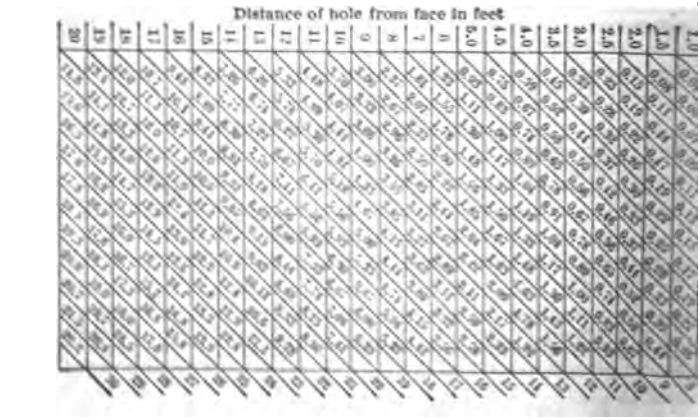
Size of drill hole for charge. If P = wt of explosive, lb; g = sp gr of ex and d = diam of hole, ft; then, $P = 0.34\,gd^3$.

6. Spacing and Pointing Drill Holes

Spacing holes in open-cut work. A common rule is to place a r vertical holes back from the face a distance equal to from 0.75 to 1 time depth, the holes being spaced the same distance apart. This usually hold in stratified rock, with holes of medium depth, but in dense granitic roc spacing must be closer. In shallow excavation the holes should seldom be f apart than 1 to 1.5 times their depth; in deep cuts the spacing may be much Hence, cost of drilling per cu yd is greater for low faces than for high.

Table 8. Spacing of Drill Holes in Open-cut Work

Distance of hole from face in feet



Depth of lift. In deep, open cuts or pits, rock is usually excavated in 2 or more ...s or lifts. Depth for economical drilling, size into which the rock breaks on ...ng, and presence or absence of seams or of horiz drill holes (called toe holes) ...ight assist breaking, all determine economic height of lift. 3½ and 3½-in ... drills are good to depths of 16 to 24 ft. Churn drills are efficient for al- ... depth, and where they are used lifts of 60 ft are common. Max depth ... drilling is about 8 ft with hand hammer, and for machine drills, 18 ft. ...le the higher the bench, the farther back from the face may the holes be ...d, but the farther back the holes, the coarser will the rock break. In deep ... explosive should be separated into several charges with tamping between; ... the entire charge is at the bottom of the hole, the bottom of the bench may ... cut and the top left overhanging. If 2 rows of horiz holes are drilled ... face, besides the vertical holes, the height of the bench may be increased.

Charging and Firing

Black powder and electric firing

Deep Hole Blasting place the dyna charge having its

If the rock consists of hard and soft layers, the charges should be ... in the hard layers. Contractor's powder and Judson powder (R R P ... are charged like black powder, but are exploded by a dynamite primer. ... grades of Judson and all dynamites are exploded with detonators. If ... powder and dynamite are charged in the same hole, explosion of the ... will detonate the dynamite.

...amite and black powder in one blast. In blue sandstone large charges of black ... and dynamite in alternate rows of holes were found effective (20). In Fig 10, ... holes were made with churn ... in bit. Holes marked "kegs" ... with 25-lb kegs of black pow... those marked "boxes" were ... within 4 ft of the top with 40% ... as shown. Before loading ... black powder, each one was ... below; first with 15 sticks of ... dynamite, second with ... with 80 sticks, and a final ... 30 sticks of 40% dynamite per ... dynamite and powder were fired together, on the theory that the powder ... the rock and the dynamite would shatter it. About 2 700 cu yd of rock were ... one blast, with 800 lb of dynamite for springing and 6 000 lb of black powder ... of dynamite for the final charges.

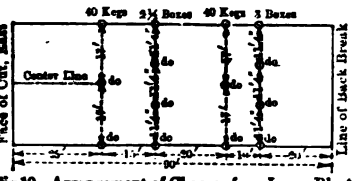

Fig 10. Arrangement of Charges for a Large Blast

...ging holes (see Sec 4, Art 8, 9). In open-cut work in stratified rock, ... black or contractor's powder, it may be advantageous, for widely-... holes, to put the entire charge in the bottom. Sprung holes are then ... In springing 20-ft holes in sandstone the first charge was 2 sticks ... dynamite, the second, 5 sticks and the third, 20 sticks, the last making ... for holding 8 kegs (200 lb) of black powder. But, in trench exca... or in deep churn-drill holes in high breasts, the charges should be dis... each having its own primer. Heavy springing is not advisable in ... shales, as it may fill the chamber with debris. In highly-inclined ... the shock of springing may cause a slip and close up the hole.

...amber blasting is done by driving a small tunnel or sinking a shaft, at the ... h chambers are excavated for the main charges of explosive. For black ... the chamber may be below the floor of the drifts, for convenience in pour... powder into large wooden boxes, built in the chambers. The tramping of the men packs it tightly, and the solid sides of the excavation offer greater resistance to the explosion. COYOTE HOLES are one-man tunnels or drifts, about 2.5 by 3 ft in size, which are charged with large quantities of explosives.

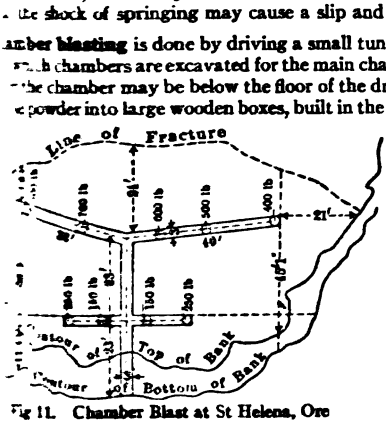

Fig 11. Chamber Blast at St Helens, Ore

Gophering is a mode of blasting used in breaking the overburden in the Mesabi, Minn, mining districts, and elsewhere, in sandy, loose ground, where vertical holes ... be kept open (20). (See *Eng & Min Jour*, Vol 88, p 696.) A hole is ... with a pointed bar, at a down angle of 15° to 20° in the side of the bank. ... cartridges, placed end to end, are pushed into the hole and exploded.

The muck is removed with a long-handle shovel, the hole deepened furt the process repeated until a hole 10 or 12 in diam and deep enough is o A chamber is made at the end by springing with 2 or 3 cartridges. A lon box filled with powder is pushed in and overturned.

Chamber blast, St Helena, Ore (Fig 11). The rock was basaltic, weighing 1 cu ft. Explosive was No 2, MV Trojan powder; charge, 3 500 lb. The tun tamped to the portal with muck. The rock was sufficiently broken to be ha steam shovel, but little bulldozing (sledging) being necessary. Cost of explosiv charging, $58; total cost of blast, exclusive of tunnel driving, $417 or 1.24¢ Volume broken, 14 280 cu yd.

Boulder blasting is done by: mudcapping or bulldozing; blockholing and ... or snakeboling. Other methods are: by sledging; by drop- ... or drop weights; by ... with fire and then ... by applying cold ... by a combination of 2 ... of these methods. ... methods: (*a*) sledg- ... drop-hammering; ... ing. Cannot be used ... ers larger than 0.5 ... yd, and it is neces- ... resort to explosives

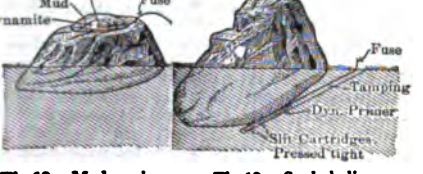

Fig 12. Mudcapping

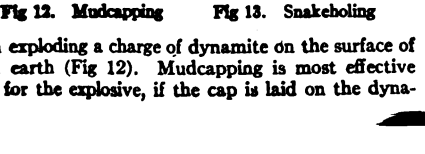

Fig 13. Snakeholing

Mudcapping consists in exploding a charge of dynamite on the surface of ... after covering it with earth (Fig 12). Mudcapping is most effective ... a depression is selected for the explosive, if the cap is laid on the dyna-

mite and not shoved into it, and if wet clay is used as a covering. Sna consists in boring a hole beneath a boulder and firing a charge in it (It is more efficient, but not so rapid as mudcapping. Blockholing co drilling a shallow hole in the boulder for a small charge of dynamite.

Average cost per cu yd of breaking boulders, from a number of recc is: sledging, 4.3¢; drop-hammer, 6.5¢; heating, 14.9¢; blockholing, 16 dermining, 17.5¢; mudcapping, 31¢; mudcapping and sledging, 32.1¢.

Table 12. Charges for Boulder Blasting (du Pont)

Weight of boulder, lb	Approx No of 1.25 by 8-in cartridges (40-60% dynamite)			Weight of boulder, lb	Approx No of 1.25 b cartridges (40-60% dy

3 000	3.5	3	1	10 000	8	6

8. Cost of Loading and Hauling

Hand work. One man will load 2 to 20 cu yd of rock (place mea 10 hr, depending mainly on size of pieces and height to be lifted.

On Chicago Drainage Canal the aver per man in 10 hr was about 7 cu yd loa dump cars. Sledging took about 14% of the time. Aver per man loading cableway skips, 10 cu yd; LARGE STONES were rolled into the skips, very little being required. In loading wagons with high sides, 1 man will average 10 cu measure (17 cu yd loose) of easily-lifted stones per 10 hr. Stones handled singl thrown off a wagon twice as fast. Stones can be loaded on wagons having sto at rate of about 13 cu yd per 10 hr, and rolled off at 50 cu yd per hr (20). C STONE can be shoveled from smooth boards or steel sheets at the rate of 13 cu measure (22 cu yd loose) in 10 hr; in shoveling from the ground or hopper-botton man will do only 7 to 8 cu yd solid measure (12 to 14 cu yd loose).

Steam shovel work. Cost in rock excavation varies greatly. In t iron ore of Mesabi range, under fair conditions, a steam shovel easily lo cu yd per hr; but, in poorly drilled and blasted rock, broken in large p shovel may do as little as 17 cu yd per hr.

Table 13. Output of Steam Shovels, Loading Blasted Rock (Origin
Compiled from one 10-hr day's work (12)

Material.....	Iron ore				Limestone			Slate, lime-stone	Por-phyry, granite	Por-phyry
Work.....	In bank		Stock pile		Quarry	R R cut		R R	R R	R R
Conditions..	Good	Fair	Fair	Good	Fair	Low face		Good	Hard	Hard

Pumping	4	7	5	2.5
Sup't & gen'l labor	6	.....	4	2.0
Total	100	100	100	50.0

...wrock Dam, Boise irrigation project, Idaho. Two Lidgerwood cableways handled ...u yd of blasted rock, boulders, gravel, and sand. Span, 1 300 ft; aver traveling ...500 ft; aver hoisting distance, 300 ft. Hoisting load, 8 tons, at 300 ft per min;

conveying speed, 1 200 ft per min. Skips, 8 by 8 by 2 ft. In July, 1912, 2-shift w Aug, Sept, and Oct, 3 shifts. Output for 4 mo, 40 624 loads, averaging 2.49 cu yd, cally all handled in 2 shifts. Cost of operation (not including loading), 37¢ per cu follows: labor, 11.1¢; power, 4¢; supplies, 1.5¢; repairs, 4.7¢; deprec, 6.4¢; prop expense, 9.2¢. Wages: laborers, $2.40 per 8 hr; cableway operators, $4 to $5; rang to $4. Power cost, 1.5¢ per kw-hr. Deprec was figured on charging off 75% of fi and all the installation cost (20).

Canal work. On St Mary's Channel Improvement, 4 cableways handled a cu yd of limestone in 2.5 yr. Rock was loaded into skips by 4 60-ton traction-ty steam shovels. Skips held 6 cu yd each, but sometimes 8 cu yd (18 tons) were h 2 cableways had spans of 1 100 ft and 2 of 800 ft. Aver haul, 300 ft. Best 1 record for all, 22 000 cu yd each; best month's record for one cableway, 30 000 cu

Cost of an aver cableway of 800-ft span and for a 5-ton load, complete with 12-in engine, but without boiler or towers, is $6 000 to $7 000. A boiler or a motor-operated plant costs about $1 500. Towers cost erected in place, $500 e Traveling towers cost 3 to 5 times as much (19).

Stone-boats are wooden or sheet-iron platforms, best mounted on runners, fo ing large stones short distances. If the runners are greased, a ton can be pulled by weighing 2 400 lb. A SKID ROAD is formed of partly imbedded round sticks of set like ties on a track 3 to 6 ft apart. A stone-boat holding 0.5 cu yd (solid meas rock can be drawn over such a road. A LIFTER or DEVIL is a wooden stretcher on 2 men can carry as much as 0.5 cu yd. On the Grand Trunk Pac R R (20), ro cheaply hauled by stone-boats on pole tracks in summer for hauls less than 600 ft, winter any distance. Track was of 2 lines of 20 to 30-ft poles, 4 to 8 in diam apart for 2-horse team and 3 ft apart for 3-horse team. Poles were joined by 2-i wood pins. Boats were of 10 or 12 logs, 7 in diam by 8 ft long, fastened togeth 1.25-in rods. In winter the track was iced; in summer, greased (1 gal per 100 ft pe In winter, a team could haul a 3-yd rock; in summer, 1.5 yd; aver load, ¾ cu yd. 500-ft haul a team and 6 men took 40 to 60 loads per 10 hr. Aver yardage p loading, 7.3 cu yd; many rocks were large and had to be blockholed. The exc comprised: 20% shovel dirt, 30% easily lifted stones, and 50% pieces 1 to 5 volume. Cost of loading, 31¢ per cu yd; cost of transport, 17¢. Wages: m $2.00 to $2.25; foremen, $3.75; cost of each horse, 75¢ per day.

Wheelbarrows hold about 0.04 cu yd solid rock; loaded by 1 man in 2 mi wheeled at 180 to 250 ft per min, losing 0.75 min per round trip. COST, at 15¢ per loading, hauling, and dumping: to a fixed cost of 18¢ per cu yd solid rock, add 6. 100 ft lead (20).

Carts and wagons. In aver rock, 1 cu yd solid equals 1.75 cu yd broken, and about 2.2 tons. Over poor dirt roads, with occasional steep rises, 0.5 cu yd (1 ton rock may be hauled by 2 horses; on hard, level road, 1.5 cu yd; aver load on good 1 cu yd (2 ton). Aver speed of haul, 220 ft per min. A 1-horse cart, on short, hill hauls, takes an aver load of 0.25 cu yd solid rock; under favorable conditions yd aver. COST BY CARTS. For short hauls, 1 driver can run 2 carts. With 4 or loading, @ 15¢ per hr, and 2 carts, 2 horses, and 1 driver @ 35¢ per hr, the l cost is about 20¢, cost of lost time 8¢, and cost of dumping 2¢, making a fixed cost per cu yd. For total cost of loading, hauling, and dumping: to a fixed cost of 3 cu yd solid rock, add 0.12¢ per 100 ft lead.

Cost by wagons. 2 men and a driver can load 1 cu yd on a stone rack in 15 mi man and driver can unload it in 7 min, or a total lost time of 22 min. Aver of each 7.5 cu yd in 10 hr. Hence, at 15¢ per hr for laborers and 35¢ for team and driver the lost time of team and driver is 12¢, and for labor loading and unloading, 23¢; hence, fix is 35¢ per cu yd solid rock. For total cost of 1-cu yd loads, add 0.6¢ per 100 ft lea

Cars on track. For tractive power of horses and resistance of ordinary cars see Sec 3, Art 5. On level track, a team will haul 2 cars of 3 cu yd rock; on slight down grade, 1 horse will haul 2 cars holding 1 to 1.5 c On good track, at slight down grade, 1 horse can haul 4 light rocker cars holding 4 cu yd, if assisted by laborers in starting. COST. If ro broken into sizes that 1 or 2 men can lift, 6 to 7.5 cu yd can be loaded pe

hr. About 4 min are lost in changing teams from empty to loaded cars, ed the track arrangement is good. Speed should be 200 ft per min. per hr for laborers and 25¢ for 1 horse and driver, lost time at pit costs of loading 20 to 25¢, and the cost of dumping, 2 to 5¢ per cu yd, hence, fixed cost is say 25¢. For total cost with 1 horse, add 0.5¢ per per 100 ft lead; for 2 horses, add 0.33¢ per 100 ft lead per cu yd, solid.

Steam-shovel loaded. In loading rock by steam shovel, the output of the attendant and locomotive is limited chiefly by the shovel output, not by the speed at which may be handled. Following work was done in a quarry of hard crystalline lime- 2 Bucyrus 95-ton, 2.5-cu yd dipper, shovels (12). SHOVEL A. First day: time, 691.5 min; lost time, 59 min, of which 41 min were for blasting, clearing tightening jacks, 13 min waiting for cars to be spotted, and 5 min idling. Sec- 138 min were lost waiting for cars, of which 87 min were spent in drilling, ling, and preparing to move, and 51 min idling. On 2 days, 197 min, or the time, was lost waiting for cars; while the cars lost on account of shovel: no reason, 7 min; moving forward, 107 min; drilling, 125 min; blasting, 67 min; track, 9 min; total, 315 min, or 25%. SHOVEL B in 2 days worked 1 290 min. 266 min or 20.6% was spent waiting for cars, of which 87 min was in idling. days, 327 min (25.4%) was lost to the trains by the shovel, as follows: oiling, setting up steam, 42; repairs, 5; waiting for cars to be loaded, 52; blasting, ing forward, 113; coaling and miscellaneous, 25 min. There were 5 35-ton motives, 4 working and 1 being overhauled. They hauled 10-car trains. 5 cu yd, weighed 4 tons, and cost $150 each. While moving the engines aver- ft per min; minimum speed 156 ft, maximum, 1 000 ft per min.

8. Quarrying (see also Open-cut Excavation, Art 10)

Kinds of stone. DIMENSION STONE is quarried and split to assigned dimensions ready ing. RUBBLE STONE is in rough slabs or blocks of irregular sizes. For dimen- ne, there must be a good WORKING FACE and usually a CHANNEL at each end, to ves. Then, by wedging or careful blasting, long blocks are secured, which are short blocks for handling by derricks. To get a cushioning effect in blasting stone, several inches of hole above the charge may be filled with hay; called tamping." For rubble or backing stone, but little channeling is done; the taken up by light blasts and large irregular slabs barred and wedged out.

Rifts and cleavage planes must be carefully considered. All sedimentary rocks and ers, as granite, have 3 perpendicular cleavage planes called the GRAIN, RIFT, and Trap rocks, diabase, diorite, porphyry, etc, often have no rift and are unfit for dimen- e. Cost of quarrying depends partly on thickness of beds and their DIP (slope) rystal. With steep dips, both thick and thin-bedded stone must usually be simultaneously; as the quarry deepens, the depth comes too great for profitable work. If joints are a quarry is a BOULDER QUARRY; if vertical and at en, BLOCK QUARRY; where there is practically no nt, but a series of horiz joints, a SHEET QUARRY.

Fig 14. Plug and Feathers

Drilling and feathering consists of splitting rocks by holes, in which 2 FEATHERS or shims (pieces of d iron, the sides of which are curved to fit the forced apart by hammering a wedge plug be- them (Fig 14).

Holes required. A granite block 6 ft thick may be in a row of plug holes 5 in deep and 6 to 8 in for a 3-ft block, holes are 2.5 to 3 in deep. s and sandstones generally require deep holes. For sandstone, holes are in diam, 4 to 16 in apart, depth being ⅔ the thickness of the block.

Drilling methods. Plug holes are drilled by hand, pneumatic hammer reciprocating drill. For shallow holes, the hammer drill is cheapest;

hand hammer next. For deep holes, a reciprocating drill on a quarry *ba* hammer drill, is most economical. HAND PLUG-HOLE DRILLING. In g 1 man can drill in 8 hr 80 ⅝-in holes, 2.5 in deep; total, 17 ft. Wit 24 to 30 in apart, and wages at 30¢ per hr, cost of splitting a block to 3¢ per sq ft. PNEUMATIC HAMMER DRILLS. In granite, 1 man ca in 8 hr 250 ⅝-in holes, 3 in deep, if the driller does not drive the plu sandstone, 4-ft holes have been drilled in 18 min, and 20 holes, 18 i were drilled at rate of 1 hole in 25 sec. BABY DRILL, on quarry bar, will 3 or 4-in hole in 0.75 min, averaging about 100 holes per day.

Cost of pneumatic plug-drilling in a granite quarry (1910): 6 drillers @ $1 air compressor operator, $3.50; 1 ton coal, $3.00; repairs, 60¢; oil, etc, 30¢; on plant, 60¢; total per day, $17. (To this add drill sharpening and plant Holes were as deep as 4 ft, averaging 18 in. Air press, 80 lb; cutting speed ave in per min. This work was formerly done by 18 hand drillers @ $1.50; total, $

Special quarry methods. BROACHING or broach channeling cons drilling a row of holes very close together, and then, with a BROACH or cutting out the rock between them. One drill on a quarry bar (Sec 1 broach per day: in granite, 10–20 sq ft; marble, 20–30; limestone, 15–35; stone, 20–40 sq ft. GADDER is for drilling rows of horiz holes near the quarry or a vertical or inclined row in the face. One drill has made 350 ft of 2-f in marble in 10 hr. TRACK CHANNELER is a self-propelling machine, tra back and forth on a 10 to 30-ft section of track, and cutting a narrow with a single bit, or one or more GANGS of bits. Some channelers cut v grooves, others can be swung at varying angles, or are arranged for unc ting. Ingersoll "Broncho" channeler is mounted on 2 parallel bars, bling a quarry bar. Channelers may carry a boiler, or be operated by or compressed air from an independent plant. Ingersoll-Rand Co bui air-electric channeler, similar in operation to the air-electric drill. Cha cost $1 200 to $3 000. In dime stone quarries (other than granite are economic necessities, becaus 20% of the stone quarried w channeling is lost in subsequent c In granite, broaching or wedging ally cheaper. Cost of running a neler is about the same as of a drill; 2 men and 0.5 ton coal p are required. COST OF CHANN LIMESTONE, N Y State Barge Can 16 consecutive months follows: Su Y-8 channelers, costing $2 800 were used. Operating crew per neler: 0.16 to 0.5 of the time of a man @ $4 per day, 1 runner @ $3.50, 1 fireman @ $2, 1 helper @ $1.75, 1 la @ $1.50. Cost per sq ft for 126 544 sq ft: labor, 22¢; coal, 2.3¢; water, repairs, 0.1¢; int and deprec, 2.4¢; total, 27¢.

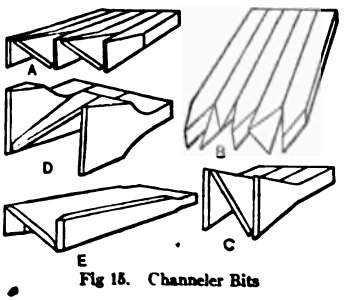

Fig 15. Channeler Bits

Standard or rigid-back channelers cut to depths of 10 to 16 ft; swing and bar channelers, 6 to 12 ft; undercutting channelers, 7 ft. Max inclin of swing-back channeler having boiler or reheater, 24°; other types, 28° bits do not rotate. In Fig 15: *A* shows the gang used in marble or rocks chip freely; *B*, that used for tough rocks which do not chip freely; *C*, for *D* is used in both quarry and contract work for sharp, gritty stones; *E* solid Z-bit, common in contract work in rough broken stone.

Table 16. Rate of Cutting with Sullivan Channelers (from Sullivan bulletins)

Marble. *B.* Hard marble. *C.* Limestone. *D.* Hard limestone. *E.* Sandstone. [illegible] rock. *G.* Slate. *H.* Soft soapstone. *I.* Tough sandstone. *J.* Gneiss. *K.* [illegible] broken rock.

Knox system of blasting. A number of round holes are drilled, and then reamed by [illegible] the shape shown in Fig 16. In medium sandstone, holes should be 10 to 15 ft [illegible] limestone, about 4 ft apart. Black powder or contractor's [illegible] will split the rock in the direction of the angles. Cost of [illegible] limestone by this system, including placing it on scows for [illegible] breakwater (1900), was 99¢ per cu yd (20).

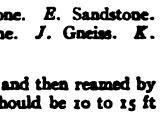

Fig 16. Knox System of Blasting

Quarrying by compressed air is practiced at Mt Airy, N C, [illegible] the granite has few joints, and splits readily in almost any [illegible]. A centrally-located hole, 2 to 3 in diam and 6 to 8 ft deep, is sprung with dynamite. Then, repeated charges of black powder, beginning with a handful and gradually increasing in size, start and extend horiz cleavage cracks. When the cleavage reaches 75 [illegible] ft in all directions, air at 70-lb press is admitted through a pipe cemented into the hole say 0.5 hr, the cleavage reaches the surface 250 ft ± from the drill hole, and the [illegible] slab is split into blocks by plugs and feathers.

Cost of quarrying. A number of detailed examples are given in (20). Cost of 93 500 cu [illegible] (measured in wall) of limestone rubble stone for Chicago Drainage Canal was 74¢ per [illegible]. Cost of thin-bedded sandstone, for dry slope walls and rubble, was 88¢ (measured [illegible] including loading into wagons. Cost of 600 cu yd of sandstone dimension stone [illegible].5 per cu yd, and of 200 cu yd of rubble stone $1 per cu yd. Cutting dimension [illegible] $6.83 per cu yd. Cost of 4 000 cu yd of gneiss dimension stone, ready for cutting, $3.55 per cu yd, and of 3 400 cu yd of rubble stone, $1.80, measured in place in [illegible]. Cost of quarrying granite dimension stone was $4.53 per cu yd.

18. Open-cut Rock Excavation

Side-hill cuts, where rock is wasted directly in front of the excavation, usually the least expensive type of open cut. Ratio of the propulsive [illegible] of black powder to its shattering effect is about 8.6, while that of dynamite is about 1; hence, it is often desirable in side-hill work to use black [illegible], so that when blasted the rock may be thrown as far as possible from [illegible].

High breasts. Quarries, of other than building stone, are most cheaply [illegible] with a high face or breast. Deep, large-diam holes by churn drills are [illegible].

Through cuts occur oftenest in canal and R R work. Depth and wi cut, and mode of removal, determine the plan of attack. Excavation in tl cuts generally costs more than in side-hill cuts.

Cost of excavating 29 295 cu yd of gneiss (mica schist) in street work in N Y pe was (20): foremen and timekeepers, 8¢; derrickmen and helpers, 9.6¢; labor loading hand drillers, 11.7¢; blacksmith and helper, 5.3¢; hauling in wagons, 40.5¢; explosiv coal, coke, oil, etc, 6¢; drill repairs, 1¢; repairs to boilers and derricks, 1.2¢; total, $1 cu yd. Four 3.5-in Ingersoll steam drills made the main holes and 2 baby drills, th holes, and hand drills and sledges broke up the medium-size stone into pieces suit building foundations. The cut ranged from 2 to 63 ft, aver lift, 12 to 15 ft. In sour 20-ft holes were drilled at an aver of 70 ft in 10 hr; in shallow drilling, an aver of n 25 ft per drill per day. There were 18 433 lineal ft of main holes (not including block Wages: 1 machine man @ $3, the others, $2.75 per 10 hr; hand drillers and sledg laborers, $1.50. Drilling plant cost $1 800; boilers, derricks, hoists, etc, $1 080; 40% mite, 20¢ per lb.

Mesabi iron range, Minn (see Sec 10). Comparative cost of open-pit and ground mining. Aver cost of stripping per cu yd: glacial drift and paint roc broken taconite, 75¢; solid taconite, $1. Mining cost in ordinary conditions: shovel, 30¢; underground mining, $1.50 per cu yd. On these bases, the cost of m column of ore 1 sq yd in area by 36 ft deep, with 65 ft of overburden, is:

Underground mining: ore 36 ft thick		$18.
Open-pit mining: Stripping 50 ft glacial drift	$5.00	
" 15 ft solid taconite	5.00	
Steam-shovel mining, ore, 36 ft thick	3.60	13.
In favor of open-pit mining		$4.

Open-pit mining is usually economical when there is not more than 1 cu yd o burden to 1 ton (say 0.5 cu yd) of ore (1 cu yd of hard slate and taconite being e lent to about 3 cu yd of ordinary overburden), and when max stripping depth is le 150 ft. As depth and track grades increase, open-pit mining ceases.

Steam shovels used in Mesabi district are Bucyrus, Marion, and Atlantic, weigh to 110 tons; the smaller for stripping, stock-pile loading, and cleaning-up wor larger for ore excavation. Standard R R cars of 100 000-lb capacity carry the ore 20-cu yd side-dump cars, the overburden. Locomotives, weighing 20 to 100 tons, side-rod and Shay types are used, the latter for steep grades. Pit tracks laid spirals are preferred to switch-backs. Aver output of shovels in stripping is 1 2 200 cu yd per shift for a 60-ton shovel, and 2 000 to 2 500 cu yd for a 90-ton; short periods, 3 000 and 3 800 cu yd respectively. In ore a 90-ton shovel should a 60 cars (960 cu yd) per shift for the season. Table 12, Art 8, gives output of a shovel as 892.5 cu yd; 90-ton shovel, 1 350 cu yd. High records per 10-hr shi 110-ton shovel, 175 cars; 90-ton, 180 cars; 60-ton, 100 cars. Contract stripping 27 to 30¢ per cu yd. Actual unit costs by company account on one property were 22¢. Aver cost of mining is about 15¢ per ton. Wages of steam shovel and crews, to 1913, but since increased, are: shovel runner, $5.97; craneman, $4.04; fir $2.50; locomotive runner, $3.75; fireman, $2.50; brakesman, $2.00 to $2.75; pitmen, laborers, $2.10 per 10 hr.

Blasting preliminary to steam-shovel work is generally done by a special crew. in overburden are by hammer and drill; in ore, by jumper. Gopher holes are dri high banks. Drilling for stripping costs 8 to 15¢ per ft of hole. In ore, 2 to 4 me an aver of 60 ft, and a max of 120 ft per 10-hr, at cost of 7 to 10¢ per ft. Gopher cost 10 to 15¢ per ft in ore, and 7 to 10¢ in stripping; 20 to 25 ft per shift are Holes are sprung with dynamite and blasted with black powder.

As navigation on the Great Lakes ceases in winter, ore is stored through 4 to 5 m in stock piles. Two systems of stock-piling are common, the Michigan and the M sota. In the latter the stock pile is started at end of a short trestle, and is built out end-dump cars (Sec 3, Art 13). The Michigan system has a long trestle. Nega Mine uses a permanent steel trestle. With wooden trestles the timber loss per y 12.5 to 25%. A trestle, 42 ft high, cost $3 per lin ft. Labor cost of stock-piling is power cost, low. Total cost varies from 2 to 7¢ per ton; where 1 000 tons per da

cost is 2 to 3¢; for small output 5 to 7¢ per ton. Stock-pile ore is reloaded by ... shovels (Table 12, Art 8).

Open-pit iron mining, near Rochester, N Y, in 1909 (20). Overburden, 20 ft, consisting of 10 ft of soil and glacial drift and 10 ft of limestone. 2 churn drills drove 6-in holes 6-ft apart, a few inches into the ore. Aver per day per drill, 4 holes (80 ft); cost, per ft, 0.09 ft of hole per cu yd. Cost per day per drill: 1 runner, $2.50; coal, 400 lb, ... supplies, 30¢; plant charges, $1; total, $5.50. Charges, 65 lb of 40% dynamite, ... lb per cu yd, costing 13¢ per lb. Overburden was loaded by a Vulcan shovel, ... a 2.5-cu yd dipper, making a 40-ft cut, 20 ft deep. It excavated an aver of 1 500 ... per day, costing: foreman, $3.50; runner, $2.50; craneman, $2; fireman, $1.75; ... coal, $10.50; oil and supplies, 50¢; 8 laborers, $10.40; plant charges, $6; total, ... Shovels loaded into 5-cu yd skips, running on an inclined conveyor, 129 ft ... and making a waste bank 60 ft high. Cost of operation per day: engineer, $2.50; ... man, $2; topman, $2; fireman, $1.75; 2 tons coal, $7; oil and supplies, 50¢; plant ... $6; total, $21.75. Total cost (not including general expense), per cu yd of ... burden: drilling, 0.6¢; explosive, 4¢; loading, 2.5¢; conveying and dumping, 1.5¢; ... 8.6¢.

... out 8 in of limestone capping adhered to the ore, and was blasted or barred off. ... were drilled through the ore 3 ft apart, and shot with 1.5 to 1.75 sticks of 15% ... size, costing 9¢ per lb. Dyna... 13¢ per lb for 40%, 22¢ for 60%, about 0.4 lb of 40% being used per cu yd for the ... shots, and 0.38 lb of 60% for springing. About 75 lb black powder equaled 50 lb ... dynamite. Cost of excavating 7 024 cu yd red granite from a tunnel approach on ... R R was $1.019 per cu yd.

11. Trenching

Overbreakage. Specifications should name a minimum width of t beyond which NEAT LINES the rock removed shall not be paid for. should also be named. Overbreakage in rock sometimes exceeds by 25 o the specified cross-section.

Depth and spacing of holes. Holes in thin-bedded, horizontally str rocks are usually drilled 6 in below specified bottom of trench; in thick-be tough limestones, etc, about 12 in below; in tough granites and traps, below.

For hand drilling in granite, holes are often spaced about 1.5 ft apart. In trench to 3 ft wide, rows, 3 ft apart, of 2 holes each, are common. In a trench 6 ft wide i trap 3 holes per row were drilled, the rows being 3 ft apart. In an 8-ft trench in g there were 3 holes per row, rows 4 ft apart.

Cost of trenching depends primarily on proper spacing and depth of

In the 6-ft trench named above, about 4.5 ft of hole were drilled per cu yd, the going to 1.5 ft below grade. Steam drills made 35 ft of hole per day @ 30¢ per ft. mite, 2 lb of 40% per hole, or 2.6 lb per cu yd of net excavation. Hence, drilling cost and blasting 40¢; total, $2.15 per cu yd. The above 8-ft trench was 12 ft deep; holes to 1 ft below grade, making 2.74 ft of hole per cu yd net. Drills averaged 45 ft in cost per ft, 23¢. Dynamite, about 4 lb of 40% per hole, or 1.1 lb per cu yd. D cost 63¢ and blasting 17¢; total, 80¢ per cu yd.

Cost of trenching in limestone, St Louis, Mo (20). Rock was in horizontal 3-ft strata, the upper 4 or 5 ft being seamy and rotten, the rest hard and difficult to b Rock was excavated 6 in below all pipes of 18-in diam or less and 9 in below larger

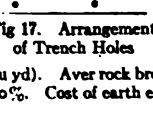

Fig 17. Arrangement of Trench Holes

Excavation was paid for to widths 1 ft greater than diam of of less than 18 in, and 15 in greater than the diam of larger Drill holes were 6 in from side of trench, and staggered 4 ft in top rock (Fig 17) and 2.5 ft apart in hard rock. Projec were sledged or shot off. Holes were drilled in 2 lifts, *top* going halfway through the ledge, bottom holes 0.66 to 0.7 thickness of ledge. Drilling was single-hand, with 1.75-in 10 ft being drilled in 8 hr. Dynamite, about 4 300 lb (2.25 l cu yd). Aver rock broken per 8-hr day per quarry man, 0.96 cu yd. Overbreakage, a 20%. Cost of earth excavation, 50¢ per cu yd. The cost of the rock work was as fol

Table 17. Cost of Trenching in Rock per Cu Yd Net Section, St Louis

Note.—Numbers in parentheses in text refer to Bibliography at end of this section.

Scope of section. The following discussion is restricted to driving of tunnels of small cross-section, the entire area of which is excavated in one operation. Most mining tunnels and adits, and many intended for irrigation and water supply, are small enough to be driven in this manner. For tunnels of large cross-section, as for railroads and some aqueducts, the work consists of two operations: the driving of an advance heading, followed by enlargement to full section. The method of work in such advance headings is essentially the same as for mine tunnels and certain of its features, of interest to the mining engineer, will be noted. In this discussion no description is given of the numerous systems of enlarging, timbering, and lining railroad tunnels, for the details of which the reader is referred to the works of Drinker (32), Prelini (48), Searler (56), and the publications of the civil and mining engineering societies.

1. Representative Tunnels

Tables I to IV contain data relating to 36 representative tunnels, most of them for mines, which will illustrate the chief features of tunneling. These data comprise: location, dimensions, kind of rock penetrated, type and number of drills used in headings, organization of work, kind and consumption of explosive, and cost per foot of completed tunnels. In other parts of this section are additional tables, giving details respecting drills and their mountings for tunnel work, repair costs, number of holes per round, and cost per foot of hole.

DRILLING

2. Choice of Drill

The prime requisite of a rock drill for tunneling is ability to perform e service under adverse conditions, and in spite of rough usage and abuse. from durability, the important determining factors in the choice of a dr rate of drilling, and costs of maintenance, attendance, and power. (See pressed Air Drills," Sec 15, Art 24–26.)

Durability. The work of a rock drill in tunneling is done under con that would quickly ruin almost any other type of machinery. Consta severe vibration is unavoidable; in many cases the drill is lubricated larly and imperfectly; dirt and grit can be kept out of the moving par by the exercise of the greatest care; the drillmen rarely understand t chine's construction and often ignorantly subject it to shocks and strai not intended to bear. To give satisfaction under such conditions r elimination of complicated details, rejection of parts not absolutely ess determination of the proper size and strength of parts, and selection of ma having proper wearing qualities. Since the pneumatic drill has been in p of development for more than 50 years, it is naturally better able to me difficult conditions of tunnel driving than any of the newer types; it is, fore, the drill almost universally used for such work at the present tim certain cases, notably the Arlberg and Simplon railway tunnels in the Al 33, 48, 52, 55, 56), the Brandt rotary hydraulic drill has been employed a tageously (see *The Engineer*, Jan 25, 1895, p 74). The perfecting of th contained electric drill is now (1913) receiving much attention. The r thus far obtained, although not conclusive, indicate that such a machin possibility to be reckoned with in the future. (Sec 16, Art 15.)

Rate of drilling is of course largely dependent upon the character c rock. Study of Table V (showing that Ingersoll-Rand and Sullivan drills, in shale and sandstone, rarely drill over 10 ft per hr, while Leyner dr granite and other hard rock rarely fall below that figure) seems to warra general statement that a hammer drill gives the higher speed in the r horizontal holes required for tunnel headings. This is probably due t mode of operation, admission of water to the hole, type of chuck, and the reciprocating steel. A piston machine strikes comparatively heavy, sma blows, which quickly dull the bit, especially if the rock be hard; after w until the steel is changed, the penetration must be accomplished by crus The faster blows of the hammer drill, being lighter, do not dull the bit so qu and the penetration is effected by the speedier action of chipping. The a cation of water, through the hollow steel to the bottom of the hole, cool bit, preserves its temper, and in flat holes removes the cuttings promptly the front of the bit. Since in the Leyner chuck the drill steel needs only inserted and given a half turn, the delay in changing steel is minimized. Fi as the bit does not reciprocate, holes are more readily started, when the face is oblique to the axis of the hole, than with a reciprocating drill.

The Brandt hydraulic rotary drill made an average of 8 to 9 ft of hole per hr i gneiss of the north heading of the Simplon tunnel, during three months of 1899. In the heading, where the rock was much harder, the average drilling speed during the same p was 5 ft per hour. The footage drilled by this machine is limited by the extremely h mounting required, which increases the difficulty of shifting and setting up. This is p offset by the fact that the machine utilizes a high percentage, 70% according to Prelini of the theoretical power supplied it, and that the exhaust water injected through the h bit, as in hammer drills, keeps the bottom of the hole clean, thus increasing the effici of boring.

Table V. Rates of Drilling in Tunnel Headings *

Tunnel	Make of drill	Rock	Speed per drill per hr, feet	Remarks

* Includes materials for drill repairs but does not include drill steel to repl wasted in sharpening or destroyed by crystallization.

† Includes labor of machinist making repairs, which is not included in the other

The attendance required by the Leyner drill is somewhat less than other machines. For most types of the larger size compressed-air pisto (also for electric machines), a runner, and a helper are required for eac and sometimes an extra man is provided for every three machines to the dulled steel. Different engineers report that from 5 to 7 men are r with the Brandt hydraulic drill. With the Leyner machine and one forms of piston drill, although a runner is necessary for each drill, one can usually attend to two drills or two helpers to three drills, and at th time keep a supply of sharp steel on hand.

Power required. The most serious disadvantage of the pneumatic its well known wastefulness of power. The lowest catalogue rating for consumption of any type of drill used in tunneling is 65 cu ft of free air p at 100 lb pressure, while drills using as much as 150 and even 175 cu min are numerous. On the basis of 20 hp for every 100 cu ft of free min compressed to 100 lb pressure, and without any allowance for loss of through friction in pipes or leakage in the machines as they become w pneumatic drill requires the application of from 13 to 35 brake hp at th

or while the drill is in operation. The Brandt rotary drills in the Simplon consumed 13 hp (the minimum figure for air drills); electric drills re- a maximum of 6 hp and some of the smaller machines run on less than

The conclusion from these data is that the pneumatic drill, because of its re- and low cost of maintenance, is best for tunnel work, in spite of its power consumption. As between the different air drills, the Leyner (now the Ingersoll-Leyner) is preferred by many for tunneling be- 1. it consumes somewhat less power and affords greater speed in drilling nearly horizontal holes required in tunnel headings; 2, it eliminates dust. reliability and its cost of maintenance and attendance are, for all practical identical with other pneumatic drills. If in the future, however, the obtained, electric drill can be so improved as to compare favorably with air drill in reliability, its lower power consumption will make it a formid- rival of the pneumatic machine.

3. Number of Shifts per Day

One shift. **Advantages:** 1. Drilling and mucking are done on separate the heading is clear when the drill-shift comes on, so that the machines set up at once and the next round begun. The drill-men and helpers, waste no time in mucking, preparatory to mounting the drills; an point when columns are used, because for setting them up the débris be cleared out down to the floor. 2. During the drilling the drill-runners helpers are not hampered by the muckers, with the consequent waste of and energy hardly to be prevented when two crews are working simul- in the restricted space of the heading. 3. Starting promptly, the holes can usually be completed within the allotted time. But, even cannot be done, sufficient extra time is available without delaying the shift. 4. The drilling and mucking shifts can be so arranged as to of time in waiting for blasting smoke to clear away: a serious con- where ventilation is poor.

One shift. **Disadvantages:** 1. Since the daily progress in driving is limited advance gained from a single round of holes, the total rate of advance Most tunnels are useless until completed. Hence, if the work is tened to the utmost, the capital invested in tunnel equipment is tied up than necessary, whence the charge for interest and depreciation is pro- increased. 2. The realization of benefits to be derived from the is delayed. For example, if a drainage adit is being driven, the ex- of ore below water level is delayed; or, if the adit is intended to lower of underground transportation, the loss on the additional tonnage in the old way should be charged against the slower method of driving Similarly, with an irrigation tunnel, an entire season's crops may because of the increased time required by the one-shift system. 3. The administration and other fixed charges is operative during the full period truction; hence, these charges per foot of tunnel will be smallest when maximum number of hours per day are employed in driving. In conclusion, the one-shift system is cheaper in wages, this economy is offset by due to delay in completing the work.

Two shifts per day permit faster progress than one shift, and if the work be duly organized there will be but little added cost per foot for excavation. muckers should begin work in advance of the drillers, and first remove the débris from the face to permit the drillers to set up their machines

promptly. If the drilling and mucking shifts begin simultaneously a drillers take part in the work of clearing back for the set-up, not only higher priced men lose time, but the two crews seriously interfere wit other. In a few tunnels, three gangs of shovelers have been required to the rock broken by two rounds. This system is obviously expensive, l the cost of the extra shovelers must be charged against an advance w but slightly, if at all, increased by their efforts; furthermore, this plan the disadvantage of simultaneous working of two crews. When two seem necessary, it is probable that a change should be made either in the and number of the holes or in some other details.

Three shifts per day. The chief advantage of this system is greate progress, because the full 24 hours are employed in driving. A certain a of crowding in the heading is unavoidable, but it is more than offset by efficiency due to the necessity for perfecting the organization. With th shift system, where drilling and mucking are done simultaneously, th know that they have some leeway before the next shift comes on, an speed is not so urgent; but with three shifts the reverse is the case muckers have constantly before them the task of removing the waste the drillers have finished their work. Conversely, the drillers endeavor t plete their round of holes by the time the muck is cleared away, so t delay may be attributed to them. Both crews are in turn inspired to work by the knowledge that they are expected to finish their labor with eight hours and that they will be followed immediately by a competing Besides, after the holes are drilled, the muckers assist the drillers in down the machines and removing them to a place of safety during bl The time spent by drillers in clearing muck and setting up machines reduced by the use of horizontal-bar mountings and by properly directi blasting the holes. Delays due to adverse conditions are not always pr able, but the men are stimulated by rivalry with other shifts to reduce t the minimum. While the ideal results of the 3-shift system are obtaine by perfected organization, still, by its adoption, the maximum efficiency realized.

4. Choice of Drill Mounting

American practice of mounting drills for tunnel work is almost evenly d between the horizontal bar and the vertical column (for details, see S Art 27), but, since drill carriages have been employed in several Eur tunnels, some reference to them will be made.

Horizontal cross-bar. The mode of employing this type of mountin best be shown by a description of its use at the Laramie-Poudre tunnel 22, 27).

As soon after blasting as ventilation permitted (ordinarily 10 to 15 min), the wo returned to the face, with a tunnel car containing the cross-bar, machines, tools, etc. The three drillers, sometimes with the assistance of the foreman, after ren any loose rock from the roof, cleared a space in the top of the pile of broken rock f or three feet back from the face and four or five feet from the roof, to get room for ha the drills. Owing to the mode of blasting employed, little work was ordinarily re to clear out the required space. Meantime, the helpers unloaded the bar and ma from the car, placed them on the rock pile, and connected the hoses to the air and mains. As soon as the necessary space was cleared, the bar was held in position b drillers and helpers transversely across the tunnel, at a measured distance from th and roof, where it was blocked, wedged, and screwed tightly in place. The ma were then mounted, the hose connected, and drilling started. As many as possi the round of holes having been drilled from this position of the bar, and the waste

sometime been removed by the shovelers (an operation which was usually finished the holes were down), the machines were dismounted, the bar lowered and reset 18 above the floor. The drills were then replaced and one or two holes drilled by achine from this position of the bar. The drilling outfit was then put on a car moved from the heading during blasting. This system, sometimes slightly modi- has been used at several other tunnels and adits with equally good results.

The **vertical column** permits a procedure similar to the above in some re- but different in certain important particulars. Owing to the vibration ed by the drills, neither method of mounting is satisfactory unless the rmly wedged against solid rock. With a vertical column the vibration ensified, because the drills are usually mounted on arms projecting at ngles from the columns, thus affording a leverage for any movement of rill. Hence a solid foundation is all the more necessary, and to secure it the débris must be removed from immediately in front of the tunnel This may cause considerable delay, even under normal conditions, ally with the 3-shift system. In the majority of cases where vertical are employed, not more than two rounds per day are attempted, and extra work of clearing away is performed by a crew of muckers before the begin work.

Carriage mounting for drills has been used with good results at the Loetsch- tunnel (21, 52, 55, 56) in the Bernese Alps, and elsewhere.

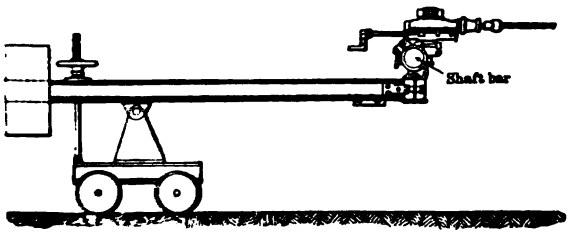

Fig 1. Drill Carriage, Loetschberg Tunnel

The first Loetschberg type (Fig 1), a horizontal bar carrying the drills was mounted end of a steel beam, which was pivoted on a truck and counterbalanced by a heavy But, even with a long beam, before the carriage could be brought sufficiently face for the cross-bar to be in position, it was necessary a passage partway through of the rock pile. While part of the material was away, the remainder being both sides of the tunnel, to moved during drilling. When age was finished, the drill was quickly moved to the cross-bar swung around and position, and drilling This carriage was super- one without the counter- beam, the drill bar being

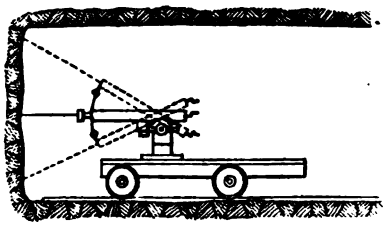

Fig 2. Modified Drill Carriage, Loetschberg Tunnel

rectly upon a short post mounted on the truck (Fig 2). With this device prac- of the broken rock had to be removed before the carriage could be brought to

The time required to begin drilling after blasting, including both tha in setting up the machines and that consumed in mucking, is an importa sideration in the choice of method of mounting. With a *horizontal bar* Laramie-Poudre tunnel (22), the normal cycle of operations was as f mucking back, 15 to 20 min; wedging the bar in place, 5 to 10 min; mo the drills and coupling the air and water for Leyner drills, 10 to 15 min. total time under ordinary conditions was 30 to 45 min, but it was not u for the drills to be in operation within 20 or 25 min after the drillers r the heading. At other tunnels using horizontal bars the time requir similar work was 30 to 60 min. When a *vertical column* is employed, to the larger amount of material to be mucked, the time consumed in s up the drills, with the 3-shift system, ordinarily ranged from 2½ to even in favorable circumstances rarely less than 2 hr. In the Loetsc tunnel the mucking time was about 1½ hr with the first type of ca and 1½ to 3 hr with the later model; but to accomplish this, nearly tw many men were employed as are usually found in American tunnel hea After the heading was cleared, however, the machines could usually be s in 5 to 10 min.

The amount of broken rock to be removed has another bearing on the lem, aside from the time consumed in clearing. To reduce delay in st drilling, it is not customary to clear the heading completely before settir much of the rock being merely shoveled to one side and removed later. preliminary work is often done by the drillers, especially with the 3-shi tem; and where (as with the vertical column) much of it is necessary, men are tired by the time the machines are ready, and consequently ca work so rapidly nor efficiently in drilling the round. On the other ha the temporary clearing away is done by the muckers, they lack stimu knowing that it is dead work and that every shovelful must be moved later. This disadvantage exists also with 2-shift work, when the mu start ahead of the drillers to clear away for a column set-up. The hori bar and, to a less degree, the drill-carriage methods have the advantage quiring a smaller proportion of duplicated work.

Adaptability of mounting. With a vertical column and piston drills, o hammer drills on a horizontal bar, the holes can be placed effectively. with either type of drill, carriage mounting is somewhat handicapped the Loetschberg tunnel it was found that, with the carriage there used holes could not be pointed to secure maximum efficiency from the expl Though the average depth of the round (about 4 ft) was much less than i center-cut system, heavy charges were necessary to make the holes bre the bottom. With the shallower holes more time was spent in the dead of setting up and tearing down the drills. Moreover, from a single set- the carriage mounting, the bottom row of holes (lifters) could not be d near enough to the horizontal to leave an even floor, and trimming was s times required to maintain the grade. On the other hand, dynamite is ch than labor, and, since shallow holes are of larger diameter at the bottom deep ones, the explosive is more concentrated. The rock is therefore br smaller and projected farther from the face, thus facilitating mucking, th at an increased cost of explosive (Art 7).

Wear and tear is less with the carriage mounting, because the drills are ke the bar continuously and are not thrown around on the floor or on the muck Thus, dirt and grit do not get into the drills, increasing friction and abrasion the cost of repairs, as well as leakage of air, with consequent loss of efficie

Facility in changing to a new hole is an important advantage possessed ... horizontal bars and drill carriages. When these mountings are ...ed, to start a new hole it is necessary only to slide the drill along the bar ...mp it in place. With a vertical column, not only the machine but the ...ing arm as well requires adjusting, and, since the adjustment is vertical ... horizontal, the entire weight of drill and collar arm must be lifted or ...ed at nearly every change.

Summing up the various factors, the horizontal bar proves to be the best ...g for tunnel work. It enables drills to be put into operation with a ... loss of time and by the fewest hands. It minimizes rehandling of ... The holes can be pointed in such a manner that the maximum strength ... explosive is utilized; deep holes are drilled, so that the time spent in ... drills is diminished, and the holes are so placed as to insure breaking ... and floor smoothly and at the desired grade. It is especially adapted ... rapid-drilling hammer machines. In common with the vertical mount... is subject to the disadvantage of allowing grit to become lodged in the ... but this can, in part, be prevented by care in handling.

5. Number of Holes per Round

Physical character of the rock is the most important factor in determining ... proper number of holes per round in a tunnel of given cross-section, and, as ... seldom twice alike, the exact number can be ascertained only by trial. ...eral, igneous rocks require more holes than sedimentary, but there are ...fferences in both classes. The holes must be spaced more closely in a ... close-grained rock, than in a brittle rock, even though the latter may be ... and more difficult to drill. Bedding planes and joints are of great assist... rendering a rock more easily broken and with fewer holes. If the number ... is correct, most of the rock will be broken into fragments small enough ... shoveled readily. The blast should be heavy enough to project a part of ... rock some distance from the face; this saves time in setting up the ma... and gives the shovelers more room, enabling them to work to better ...ntage on the scattered material. Table VII shows the number of holes ... used in American tunnels, for different kinds of rock.

6. Arrangement of Holes

The arrangement of drill holes, greatly influenced by local conditio arely the same in any two tunnels; but nearly all the systems adopt merican mining tunnels may be classified under three heads, according t ype of cut employed.

The "cut" or "cut holes" are those which are pointed in such manner that, lasted first, they remove a core or wedge of rock from the solid face, thus decreasir ork to be done by the remaining holes.

The wedge or "V" or center cut, the one most commonly employed, ists of several pairs of holes directed toward each other from opposite sid

...sing. They break out a wedge-shaped prism, usually extending from ... to roof.

... 3 shows a typical wedge cut, like that of the Buffalo Water tunnel (6, 39, ... Holes 1 to 8 comprise the cut and were blasted simultaneously by elec-

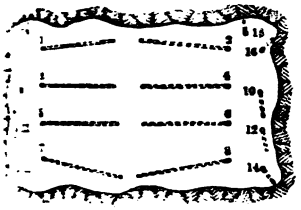

Fig 3. Wedge-cut Round of Holes

Fig 4. Wedge-cut Round for Arched Headings

... Side holes 9 to 14 were next fired together, the back holes 15 to 18 ... fired last.

For arched or semicircular headings the arrangement of holes is somewhat ...ied. Fig 4 illustrates the round used in the headings of the large siphon ... of the Catskill Aqueduct (10, 38, 41). The cut holes 1 to 6 were blasted ...er, followed by the "relievers" 7 to 12 and finally by the "trimming" ... to 22.

With a horizontal-bar mounting further modification is necessary, though ...eneral arrangement remains the same. Fig 5 shows a round employed in ...aramie-Poudre tunnel (22). Holes 1 and 2 were called "short cut" holes; ... "long cuts"; 7, 8, 9, 10, 19, and 20, "relievers"; 11 to 14, "sides"; 15 to ...acks"; and 21 to 23, "lifters"; the numbers indicating the order of

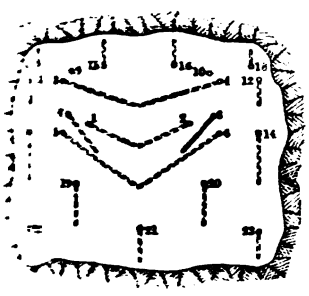

Fig 5. Wedge-cut Round Drilled from Horizontal Bar

...ge. The lifters and two relievers, 19 and 20, used only in hard ground, ...e only holes drilled from the lower position of the bar. Three machines ...employed per round, the left-hand machine drilling holes 17, 11, 5, 13, 7, 1, ...d 22; the center machine drilling holes 16, 10, 15, 9, 3, and 21; the right-...machine drilling holes 18, 21, 6, 14, 8, 2, 20, and 23, in the order stated.

The pyramid cut consists usually of four holes, drilled so that they or nearly meet at a common point (generally near the axis of the which, when properly blasted, remove a more or less pyramidal core. shows a round of this type as employed at the Yak tunnel (Tables I No 36), in which the cut holes (numbered 1) were blasted simultaneou lowed by the remaining holes in the order indicated. In most cases the cut is made with vertical columns, but it can be drilled just as effectiv the horizontal bar, by making 2 or possibly 3 holes with each machine f lower set-up (Fig 7).

The bottom or draw cut (Fig 8) has been employed at a number of of which the Carter (Tables I to IV, No 3) is typical. The holes were in the order indicated, 1 to 3 comprising the cut. This method often fa

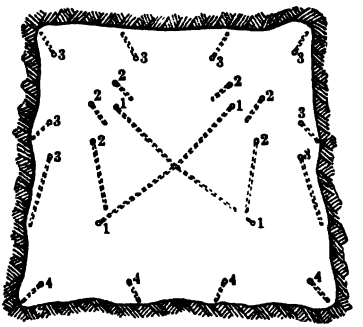

Fig 7. Pyramid-cut Round Drilled from Horizontal Bar

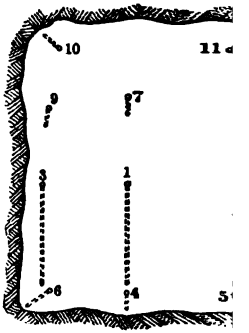

Fig 8. Bottom-cut Ro

the only solution for placing holes in a small tunnel, in which it is impract to drill an effective wedge or pyramid cut. The cut holes should be from as near the top of the heading as possible, and so directed that th be assisted by "lifter" holes (Fig 8, Nos 4, 5, 6), both rows being blast gether.

Importance of the cut holes. It can be proved theoretically that, w hole is drilled in homogeneous rock, the maximum efficiency is obtained the charge when the "line of least resistance" (the shortest distance fro charge to a free surface of the rock) is at right angles to the axis of the and that the minimum efficiency occurs when the two coincide. Althou practice a homogeneous rock is rare, and the results of drilling and blasti quantitatively influenced by differences of rock texture and the preser absence of bedding planes, joints, and cracks, yet these results are found in general agreement with the theoretical deductions. It is obvious that tunnel heading, where there is but one free face, it is impossible to dril blast a single hole in such manner as to produce maximum efficiency. with a number of holes, arranged according to any of the preceding sys and blasting the cut first in order to increase the area of free surface, bett sults are secured from the remaining holes. Hence, the position and dire of the cut holes are of prime importance, the others being merely spaced ficiently close together to break the rock small enough for easy handling.

The angle between opposite holes of the cut should be as wide as can be ...ed with a given depth of round, so that the line of least resistance may ...rmate a perpendicular to the axis of the hole. Therefore these holes ...d start as close as possible to the opposite walls of the heading, keeping ...w the necessity for leaving sufficient space for handling the bits and feed... drill. For these requirements in narrow headings a greater proportion ...e total width must be sacrificed than in wide headings; in the latter an ...ntageously wide angle is easily secured.

...onnecting cut holes. Owing to mechanical reasons, the gauge of drill bits ...e decreased with each successive change of steel; the hole is therefore ...st at the bottom, just where it should be as large as possible, to con...e the charge. This defect can be partly overcome by drilling opposite ...s so that they connect, thus concentrating the explosive at the point of the ... It is specially desirable to do this when firing with fuse, because of the ...al impossibility of gauging the lengths of two fuses to make them det... their charges simultaneously. Furthermore, the combined efficiency of ...o connecting charges is greater than when exploded separately. Assum... that the holes are in homogeneous rock, and that they make equal angles ... the free face, if the charges are detonated simultaneously their maximum ...ng effect will be exerted along the resultant of their forces, which theo...ly coincides with the line of least resistance. The result may be some... modified in practice, but it is an established fact that where the ground ...gh and difficult to break, better results are obtained by drilling the cut ... to intersect.

7. Depth of Hole

Advantages of shallow holes. 1. With properly directed holes, an in...ed efficiency is obtained from a given charge; for, since the width of the ...g is practically constant, the angle between the line of least resistance ...e axis of the drill hole is a function of the depth of round. The width of ...ade, therefore, and hence the efficiency, increases with shallow holes. ...e holes may be of larger diameter at the bottom, thus increasing their ...ity for explosive and concentrating it where most needed. 3. Since drill ...e not charged to their full depth, the mass of rock between the outer ... a charge and the free face (which may be considered a measure of the re...e to be overcome) is not so great. 4. The rock tends to break into ...r fragments. 5. The rock is projected farther, instead of being piled ...mediately in front of the new face. This facilitates mucking and saves ... setting up the drills. 6. The same care is not required in starting ...w holes, nor is it necessary to direct them with so great accuracy; never... the desirability of connecting the cut holes must not be overlooked. ... entire cycle may be completed in a single shift. Men do not work so ...without rivalry or special incentive, and it is important to have an accu...measure of the work done by each shift. In most cases there is a sufficient ... of time for ordinary delays.

The chief disadvantage of shallow holes is that a greater number of rounds ...e made to secure the same daily advance. This results in waste of ... time; for, under ordinary conditions, one hole of a given depth can be ... quicker than two holes of the same total footage, because of the time lost ...ging to a new position. Though the difference in drilling time itself ...ly small, each extra round required to make a given advance causes ... time in charging and blasting, waiting for smoke and gases to be re-

moved, clearing the débris from the face, and in setting up the drills, all o is unproductive work.

The above conclusions are substantiated by the results obtained from shallow in the Loetschberg tunnel, previously cited.

Length of tunnel: 47 676 ft, driven from the two end headings only. (Headi holed through, March 31, 1911; total time, 53 months; by machine drills, 46 51 driven in 1304 days.)

Bottom heading: 6 ft 6 in. high by 10 ft wide (nearly same size as some doub mine tunnels).

Rock: hard granite and gneiss.

Holes per round: usually 12 to 15; depth, 4 ft; diameter at bottom, 2 in.

Arrangement of holes: 4 vertical rows, of 2 to 4 holes each; all nearly normal

Drills used: from 4 to 5 Ingersoll-Rand, F-94, 3½ in diam.

Approximate time for a complete round:

	Mi
Setting up drill carriage and cross-bar	
Drilling	
Removing carriage from heading	
Charging and firing	
Clearing out smoke	
Mucking through middle of rock pile to make room for setting up carriage	
Total time (4 hours)	

Work carried on in three 8-hr shifts, each shift drilling and firing two rou which basis the normal rate of advance would be 7 ft per shift, or 21 ft per 24 hr rate was reduced by ordinary delays to a general average of 18 ft per day, in each h The maximum advance in any month was 944.6 ft (28 days), or 33.7 ft per day (39, 55).

The advantages resulting from a change to a shallower round were str brought out in the Laramie-Poudre tunnel (9, 22).

During the 7 months from April 1 to Oct 31, 1910, at the east end of the tunnel, were driven (average, 453 ft per month) using a round 10 ft deep in a heading wide; but during the next 8.8 months, from Nov 1, 1910, to July 24, 1911 (wh tunnel was holed through), 4 798 ft were driven, or an average of 545 ft per with a 7-ft round. This 22% increase of speed was made notwithstanding that th was farther from the portal; and, since there was no change in equipment or ch of rock, it may be attributed solely to the shallower holes. For an advance of 9 ft with 10-ft holes, it was unusual to drill and blast more than two rounds in (frequently less), as the daily average of 14.5 ft testifies. But with 7-ft holes, n could 3 rounds be made, advancing an average of 6.5 ft each, but a good margin was left for delays, which often meant increased footage. Thus, in March, 191 American hard-rock monthly record of 653 ft, or over 21 ft per day, was establis

At the Rawley tunnel (51), in driving through andesite, 8 ft holes were drill heading 7.5 ft wide. The cut holes were blasted separately, and it was usually sary to reload and shoot them a second and occasionally a third time. The cyc therefore lengthened to about 10 hr, and sometimes 14 hr were needed. Lat depth of hole was reduced to 5 ft, making it unnecessary to shoot the cuts sepa thus, instead of only two 7.5-ft rounds in 20 to 22 hr, by working 3 shifts it was p to drill and blast four, sometimes five, 5-ft rounds per day. This increased th progress from 15 to nearly 23 ft, at small added cost for labor and with a decre fully 25% in the cost of explosive.

The most economical depth of hole must be determined by trial in ea dividual case, because of the numerous variables influencing the result. Us a depth of round of from 60 to 75 % of the width of the heading will be satisfactory. Table VIII gives an analysis of American practice:

Table VIII. Depth of Round in American Tunnels

	Type of cut	Height of heading, ft	Width of heading, ft	Average depth cut holes, ft	Average depth other holes, ft	Average depth round drilled, ft	Percentage average depth of round to width of heading	Rock

BLASTING

8. Choice of Explosive

(See Section 4 for full treatment of Explosives)

A suitable explosive for tunneling, or other underground service, shou
duce the minimum of poisonous gases; should not be easily affected by m
nor by changes of temperature. Gelatin dynamite fulfills these requi
and is almost invariably used in American tunnels, although ammonia dy
was employed in some tunnels of the Los Angeles aqueduct (completed,

The proper strength of explosive for a particular case must be dete
by trial. Such widely divergent results are obtained in different localiti
the same grade of explosive and in apparently identical rock, that it is
to be dogmatic, even with accurate knowledge of local conditions. Gen
tough, close-grained, igneous rock requires a stronger dynamite, while
mentary rock (or an igneous rock that has been altered, weathered, c
tered) can be blasted as effectively with a lower grade of dynamite.

A notable example of the use of very high-grade explosives is that of the R
tunnel (4, 18), where for the tough, close-grained Pike's Peak granite, "100 %"
dynamite (blasting gelatin) was required to obtain satisfactory results. It is
to have been the first dynamite of this grade used in tunnel work. Table II
grades of dynamite used in a number of American tunnels.

Different grades in the same hole. The practice of loading the bot
a hole with high-grade dynamite, and using 40 or 60 % for the remainde
charge, is not uncommon, especially in the Western states. It prod
greater disruptive force at the bottom of the hole, where most needed.
practice entails the inconvenience of handling two different grades of dy
both in the heading, and in the thawing-house. In some cases equally g
sults might be secured by the use of lower grade dynamite in shallower
or a change in the type of cut. But for very hard, tough rock, it is a
practice and reduces somewhat the cost of explosive.

9. Quantity of Explosive

Data on the quantity of explosive used in American tunnels are g
Table IV. It will be seen that the general average consumption is 5.75
cu yd. The consumption of explosive in the Simplon and Loetschberg
ings was somewhat higher than this; at the Simplon the average charge
heading was 6.5 lb per cu yd, and at the Loetschberg the average from Ja
1908, to July, 1910, was 6.0 lb of 85 % dynamite per cu yd in the north
ing and 6.86 lb in the south heading (55).

10. Charging the Holes

Position of the primer. Opinions differ as to the proper position
primer (*i.e.* the cartridge containing the detonator). Some maintain
should be the outermost cartridge; others, that its proper place is at
the bottom of the hole. In our opinion the best practice is to place the
at top of charge, preferably in next to last cartridge, thereby protecting
nator during operation of tamping.

Advantages of inserting primer last. 1. The danger of igniting the dynam
side spitting of the fuse is eliminated; the dynamite thus being detonated and not

efficiency of the explosive is obtained and the resulting gases are not so injurious. ...ans that when the fire in the fuse travels past the full length of the charge, there is ...e that the flame may burst through the fuse covering and ignite the dynamite. 2. The ...e of dynamite is more likely to be well compacted, leaving no air spaces to decrease ...ness of the explosion. When the primer is the first or second cartridge in the ...e remaining cartridges (especially the one next to the primer) can not safely be ...roughly compacted.

...disadvantages of inserting primer last. 1. It is maintained that primer is liable ...ut off by the explosion of a neighboring hole. Possibly this might happen, but ...would be a strong indication that the hole was misplaced or too heavily loaded. ...fuse may be torn out by flying débris. The remedy is simple: before igniting, ...se carefully close up to the mouth of the hole. 3. To insure that the explosive ...reach the bottom of the hole, a stronger detonator, or a higher strength explo... ...ld be used. The latter remedy would have the effect of reducing the length ...e in the hole, since a smaller bulk of explosive would suffice.

...e. — It is sometimes desirable to prime bottom cartridge for rotation blasting; in ... cartridge must not be slit, and fuse must be of best quality (Sec 4, Art 9).

...se of tamping. Tamping is absolutely necessary, to develop the full ... explosive, to assure complete detonation, to minimize noxious fumes, ...reduce the flame. Unless thoroughly tamped, many explosives do not ...e completely; all give worse fumes, and in tunneling the cut holes should ...mped with special care, to prevent them from blowing out. Even water ... in down holes) is inferior to sand, and it is good practice to tamp ...ed holes with rock screenings.

...e tunnel men hold that any gain in efficiency of explosive is more than ...by the disadvantages of using tamping; as causing delay in charging and ...cience in cases of misfire. Notwithstanding this, the omission of tamp... ...ur practice, largely the result of prejudice. Much of the common over... ...of holes in tunneling could be obviated by proper tamping. In case ...re, never pick out tamping; drill and fire another hole at least 2 ft from ...e.

...rozen dynamite. Chilled or frozen dynamite should always be thawed ... use. This is necessary: 1, for the safety of the men; 2, because frozen ...ite can not be properly compacted in the hole; 3, because the full force ...en dynamite is not developed upon detonation, whence a loss in effective... (Sec 4, Art 7.)

...paration of primer. (See Sec 4, Arts 8 and 10.)

11. Firing

...e fuse. For a small round of holes the fuses are lighted by one man; for ...r number there should be two men, the best practice being for them to ...ultaneously the fuses of corresponding holes, each calling out the hole ...nts it.

... of the fuse projecting from the mouth of the hole should be closely coiled and ... split for ½ to ¾ in to expose the powder train. The lighting may be done ... ways: by a candle or acetylene lamp (spit of fuse may blow out flame and ... in the dark); better, by a "spitter," consisting of a short piece of fuse which ...shed and partly severed, at intervals of about ½ in, to expose the powder ... fire travels along the spitter, and on reaching one of the cuts flares violently ... side, and, if directed towards the blast fuse, is almost certain to ignite it prop... 4, Art 8). The firer should light each fuse separately, instead of bunching ... attempting to ignite all at once.

Fuse igniters. In very wet tunnels it is sometimes necessary to us igniter. One form consists of a short celluloid cylinder, closed at one containing gunpowder or other explosive. It is slipped like a cap on of the fuse, which is cut square. The celluloid itself is ignited by a c other means, and, being unaffected by dampness, burns strongly until it charge is reached. A flash then takes place, which lights the fuse. not very reliable, as the fuse wrapping may burn some time before pow is reached.

Electric firing. When ordinary electric detonators are employe necessary only to connect the fuse wires and pass a current through the current may be taken from an electric light or power circuit, or gene a hand-operated magneto or dynamo. All the holes are exploded neously. (For details, see Sec 4, Art 8.)

Delay-action detonators (Sec 4, Art 10) make it possible to explode consecutively, singly or in groups, with a single closure of the circuit resemble ordinary electric fuses, except that the platinum bridge does plode the mercury fulminate directly, but ignites a short train of gu inside the detonator, which requires an appreciable, though short, burning before it reaches the fulminate. By making the powder trai different lengths, two delays are obtained; or, if these be used in co with an ordinary detonator, the blasting may be performed in three sta

When using these devices in tunnel work, special detonators, called "No (Sec 4, Art 10), are generally placed in the cut holes, a "first delay" in the relie the "second delay" in the remaining holes. Delay-action detonators might made with other lengths of powder train. A fourth stage is needed for the li cause a part of their function is to project the material broken by the other h the immediate front of the new face; and, with the horizontal bar mounting, a is also desirable for delaying one lifter in order to throw the material away side of the tunnel where the capstan end of the drill bar is to be placed, thus space for manipulating the jack bar.

Advantages of electric firing. 1. Certainty of detonating all the cut h ultaneously. With fuse firing, when two cut holes are connected at the bott will explode as one; but it is impossible to make several pairs of holes, as in cut, explode together because of the variation in burning rate of the fuse, no ma exactly the lengths are proportioned. 2. Absence of smoke and noxious gase by burning of the fuse. Tests by Bureau of Mines show that a large part of t from burning fuse is carbon monoxide. 3. Charge may be ignited from a place o thus lessening dangers from premature explosions. 4. No time is lost in wa misfires.

Disadvantages of electric firing. Electric detonators cost more and trouble in keeping the leading and connecting wires in good condition, for they sarily damaged by every blast. When delay-action detonators are not used, must return to the heading after shooting the cut holes and connect the wires le the holes to be fired in each of the succeeding groups. As some time is required smoke to clear, and considerable shoveling may be necessary to uncover wire have been buried by the previous blast, it takes longer to fire a succession of h this manner.

12. Precautions

(See Sec 4, end of Art 7, as to precautions in handling, storing, th charging and firing.)

MUCKING

13. Men Employed

Size of the mucking crew. Time saved in mucking is especially important in the vertical-column drill mounting, because the set-up for a new round cannot be made until the heading is cleared. With the horizontal bar the mucking should be finished by the time the upper holes are down; if the shovel-crew is too small to accomplish this, setting up for the lower holes is delayed. Prompt removal of the muck is always essential, for many little things are to be done after the heading is clear, and reserve time is valuable. On the other hand, if the mucking crew be too large, the men will interfere with one another. Analysis of work in a number of tunnel headings shows that a shoveler requires about 5 ft width of floor space. That is, in a tunnel 10 ft wide there should be no more than 4 shovelers; in a 6-ft tunnel, only two. Besides these, a man or two should be employed for picking down the muck in front of the shovelers, handling large rocks, assisting in the handling of the cars, or doing other things to make for speed. Hence, in tunnels from 6 to 10 ft wide, the mucking crew should range from 3 to 6 men.

Alternate crews. In the Loetschberg and other European railroad tunnel headings, two sets of muckers were employed, one resting while the other was working. This tended to greater speed, because men can work harder for the few minutes required to load a car, if allowed an equal interval of rest. But, although this plan expedites mucking, the gain would hardly warrant such procedure where wages are high. At the Loetschberg tunnel the shovelers received $0.80 per day, as compared with $3.00 or $3.50 for like work in the western United States; hence the Loetschberg double crew of five shovelers would entail in this country an extra cost of $15.00 to $17.50 per shift, against $4.00 in Europe. Since the advance per shift in America rarely exceeds 7.5 ft, the extra cost of double-crew work would be at least $2.00 per foot of tunnel.

14. Positions of Working

The advantage of a rest from the severe work of shoveling can be obtained without employing extra labor, by shifting the men's positions systematically, as a number of American tunnels. In the Laramie-Poudre tunnel (13, 22), the muckers worked as follows:

When car 1 was filled, two shovelers, designated as A and B, took it to the rear, the two others (C and D) jumped to empty car 2, which had previously been thrown to side off the track, set it on the track and pushed it into position for loading. Meanwhile the remaining men (E and F) stopped picking down the rock pile, took the shovels of A and B and assisted C and D in filling car 2. Car 3 was then brought up by A and B close to where car 2 was being filled, and was thrown off the track on its side in the position formerly occupied by car 2. A and B then picked down the rock pile for the other men, while car 2 was being loaded. When filled, this car was removed by C and D while E and F set up the third car and loaded it with the help of A and B. A fourth empty car was meanwhile brought up by C and D, who then took their turn at picking down. The cycle was completed when E and F took the third loaded car to the front, brought back another empty and resumed their original position on the muck pile. Each man spent two-thirds of the time in tramming or picking down the rock pile, which is easier work than loading, and suffices to relieve the monotony of shovel-

In methodical procedure there is no confusion, no lost motion. The foreman rarely has to give an order, and does not shout at the men constantly, a bad habit unfortunately common in many tunnels; nor do the men waste time by running to the foreman for advice in minor matters.

Rapid work is attainable by the system described above. Cars of 1 capacity at the Laramie-Poudre tunnel were filled in an average of 3 or At the Rawley tunnel (51), where a similar system was used with four sh 25 cars of 17 cu ft each were loaded in 2 hr; in another case, 20 cars in including all ordinary delays incident to making up trains. Taking in sideration the number of shovelers, these figures of 5 to 6.75 min per c the Laramie-Poudre, and 7.5 to 8 min at the Rawley, compare favorab work in the Loetschberg tunnel, where 5 min were required to fill a 1-c (35.5 cu ft) by a crew of 10 men, with an extra minute to replace it, wh with an empty one.

15. Handling Cars in the Heading

A common system is to tram the cars by hand from the face to a where they are made up into trains and hauled to the portal by the m transport provided. The disadvantages of this plan are: 1, the swit siding must be moved frequently, to keep pace with the tunnel advan they will soon be too far from the face; 2, an unavoidable loss of time the loaded cars are being removed and the empties brought up, beca switch can not well be nearer than 100 ft from the face, and it is often 500 ft; 3, the loaded car must be moved by hand to the siding before the can pass it.

Loading on alternate tracks has some disadvantages. The extra l laying two tracks in the heading, instead of one, which can not be don mucking is finished, may delay starting a new round. Also, the econom for keeping the switch near the face is not so apparent with this method the other, so that shifting the tracks is apt to be neglected, and time wa the trammers. Loading on alternate tracks only partially obviates the of derailments in crossing switches.

Steel plates. The necessity for two tracks can be avoided by cover floor of the heading with steel plates for 30 or 40 ft back from the face cars can easily be jumped from the end of the track on to the first of these and pushed up to the muck pile. When one car is full, an empty one can be shunted into position for loading while the full car is being moved t the siding. This simple method is especially advantageous for larg The steel plates also facilitate mucking, since the broken material is sh from them with less labor than from the rough and irregular rock floor tunnel.

The best method, in most cases, is to use small cars; then the empties tipped off the track to allow full cars to pass, and can be righted and pu by two men, thus avoiding the complications and extra work arising fr use of switch and siding. The details of this system were well worked the Rawley tunnel.

On reaching the heading, the empties were pulled as near as possible to the f which ordinarily stood on the track some 75 or 100 ft from the face. The mule w detached from the empty train and pulled the full cars back to the one being usually the last one of the previous empty train; or, if all had been loaded, the f were pulled as near the face as possible. The empties were then hauled up to the cars and tipped off the track. All this was done by the mule and driver alone, when the shovelers had completed loading and could therefore assist. After the train had started for the portal, the muckers took the two empty cars nearest the set them on the track and pushed them to the face, where one car was again tip on its side while the other was being loaded. Getting the loaded train out of the h and an empty car in position again rarely occupied more than 3 to 5 min. The rem of the cycle was similar to that in the Laramie-Poudre tunnel, already described (A

The advantages of this system are: 1. It does away with the trouble arising from having a switch near the heading. 2. It requires the use of small cars which leave more room for the shovelers. As the sides of the smaller cars are lower, they are easier to load, and to handle in case of derailment; and, as fewer men are required for moving them, more of the muckers' time is spent in actual loading. 3. The cars have to be hand-trammed only a little more than the length of one train, this distance being constant and not varying as the tunnel advance. 4. The minimum time is consumed in replacing a loaded car by an empty. 5. Time is saved in making up trains.

TIMBERING

16. Materials

Artificial supports of timber, brick, stone, metal, or concrete may be used in tunnels. Timber is in general use, because of its cheapness in many mining districts, and the readiness with which it is cut, framed, and placed in position. Even when the permanent lining is to be of masonry or concrete, temporary timber supports are usually put in first, as the work advances.

Seasoned timber is desirable, because it better resists decay. The bark should always be removed from round logs; the space between it and the wood forms a breeding place for wood-destroying insects, while the bark itself collects and retains moisture, thus encouraging the growth of fungi and hastening decay. *Round timbers, peeled and seasoned*, are more durable than sawed timber because the sharp corners of the latter are especially liable to decay. In round and small timber, commonly used for mining, the outer half of the log is almost entirely sap-wood, containing starch, sugars, proteids, and soluble nitrogen compounds, which are the foods upon which decay-producing fungi live; they are nearly absent in the heart-wood (Sec 43, Art 20).

The corners of a square timber consist largely of this easily infected sap-wood. In timbers the corners of sawed timbers 3 or 4 years old are often so decayed that they can readily be pried off to the heart-wood. Though the outer portion of a round timber consists of sap-wood, the cells have not been ruptured by the saw and the fungi do not readily find lodgment. Round timbers, however, are not so easily handled as square; they can not be so readily alined, nor reinforced by false sets or pieces. Where timber is transported long distances, the greater weight of round sticks (especially when they are truncated cones or "churn shaped," instead of being nearly cylindrical) cause greater freight costs, and square timbers should be used. Under such conditions the saving in transportation charges will pay for a preservative treatment, applied to the timbers before being placed underground.

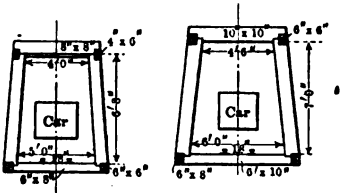
Preservatives. The best method of checking the growth of fungi is to poison the source of their food supply. Most of the preservative processes depend on the injection of zinc chloride or creosote. The former is not suitable for wet places, as it is soon leached out of the timber. Creosote, properly applied, will last much out, and is therefore the preservative generally employed for tunnel timbers. It is somewhat more costly than zinc chloride and, being a liquid, the transportation charges also are higher (Sec 43, Art 20).

For **permanent tunnel linings** brick and stone were formerly the chief materials used, and most of the older railroad tunnels are lined in this expensive manner. Steel beams are sometimes employed as roof supports in the main haulageways and gangways of coal mines, and their use is likely to extend as timber becomes more expensive. Concrete has thus far been restricted chiefly to tunnels for irrigation, or water-supply tunnels, but it will probably be applied in future to important mining tunnels, where a permanent lining is necessary (Secs 44, 46, 57, 59).

17. Types of Timbering

The simplest form of roof support is a horizontal timber, set at each a "hitch" or recess in the wall. When the sides of a tunnel are not enough to afford reliable hitches for this timber, "posts" are placed un ends, and it is then called a "cap." If the floor is weak the posts res sill, thus forming a *four-piece set*. When the roof pressure is too grea carried by a horizontal cap, the upper member is divided into two o segments, forming the *rafter or arch set*.

Four-piece sets. Fig 9 shows a four-piece set of timbers, comprisi posts, and sill, for as small a tunnel as is usually advisable. The main t are 8 by 8 in, and the posts are held apart and side pressure resisted by 8-in plank spiked to the cap. Horizontal collar and sill-braces are also



Figs 9 and 10. Four-piece Sets

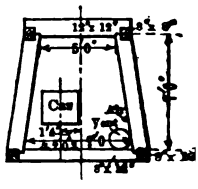


Fig 11. Set for Haulage and M

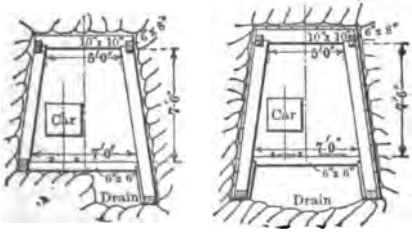
Fig 10 gives the dimensions for a similar set in a larger tunnel. The t are 10 by 10 in and the joint between cap and posts is beveled at the c for resisting both horizontal or vertical pressure. For heavier ground th and cap may be made of 12 by 12-in timber, with 8 by 8-in collar-brace single-track tunnels for a considerable traffic, it is often advisable to ma net cross-section large enough for a manway and ventilating pipe on on and car tracks on the other (Fig 11). For carrying a considerable volu



Figs 12 and 13. Sets for Drainage Tunnels

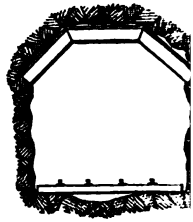


Fig 14. Arch Set without

water, the design shown in Fig 12 is satisfactory, notwithstanding the fac the timbers are unsymmetrical. The 6 by 6-in sill, which also forms th tie, is not notched into the post at the right side, but is supported by a 10-in plank spiked to the post, the upper end of the plank being recessed to receive the sill. For still larger volumes of water, the design in Fig recommended. The quantity of water and grade of tunnel determine the p depth of the drain.

Arch sets. Sometimes the tunnel walls are firm and only the roof needs port (Fig 14). A carefully constructed footing for the arch timbers is requ

...e tunnel at the shoulders, and calls for 30° bevel joints throughout, thus ...g the side and top pieces of the arch interchangeable. Fig 17 illustrates similar timbering for a double-track tunnel. Some constituents of certain rocks oxidize on exposure to the air, softening and increasing in volume to such an extent that the excavation tends to close in from sides, roof, and even the floor. For driving through such swelling or creeping ground, the sets may be designed as in Fig 18, where drain and track are protected by an inverted arch. If 12 by 12-in timbers of this form will not resist the squeeze at the usual distance of 4 ft between centers, the sets must be spaced closer. Where zones of rock are encountered that can not be held even by this expedient, the sets may be placed 3 or 4 in apart, the decomposed rock in line with the spaces between the posts being picked out to a depth of 4 or 5 in back ...e timbers. Swelling ground is usually soft, so that this can readily be done. ...g the tunnel subsequently with concrete, access of air to the rock is pre... thus permanently overcoming the difficulty. The octagonal set (Fig 19)

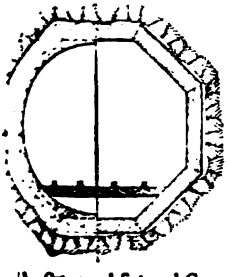

Fig 19. Octagonal Set and Concrete Lining

offers another means of supporting very heavy ground. For importan it is advisable to follow up the timbering with concrete, placed in front between the sets, as shown in the cut. In this case, to insure the sa the tunnel after the timbers have decayed, the sets should be spaced r than 12 in apart (15 to 18 in is still better), because the wider opening room for a stronger rib of concrete between the sets. The octagonal

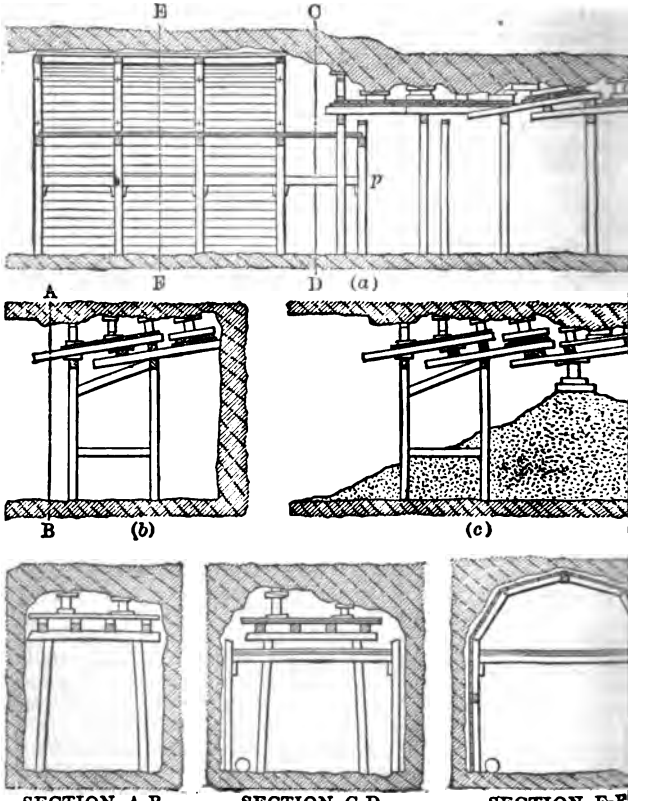

Fig 20. Elizabeth Lake Tunnel Timbering (*Mines and Minerals*)

easy to handle and where the flow of water is not too great for the dra area below the tracks, nothing better can be adopted. All the pieces in set are alike, which is a convenience in framing, storing, and erecting the

Speed of work. The system of timbering employed in the north he of the Elizabeth Lake tunnel (Fig 20) affords a good example of speed efficiency in placing timber sets. In this end of the tunnel, of which 13 were timbered, the average monthly advance was 340 ft, as compared

for the south heading, where only 3 424 ft of timbering were required in ... 13 500 ft (37).

... main tunnel (12 by 12 ft) was preceded by a short pilot heading, about 8 by 8 ft, ... of which was supported by "false" timbering. 18. Concrete Linings

... lining a mine tunnel the concrete is usually placed in the spaces between ... timbers and for a few inches in front of them. Where the sets are not ... too closely this is generally sufficient, even though decay of the wood ... causes weak spots in the lining. This defect can be avoided by the use of ... and caps of reinforced concrete instead of wood, a practice which finds ... wherever its greater expense is warranted. The concrete posts and caps ... made outside of the tunnel, in a mold which gives them the exact form of ... pieces, and by proper reinforcement they can be made equal, if not ..., in strength to timber. In water-supply tunnels a continuous con... ... lining performs the added function of preventing eddies and friction caused ... otherwise irregular walls, for which reason such tunnels are generally ... throughout, irrespective of the need of the roof for support. In the ... Angeles aqueduct the lining is at least 8 in thick where the tunnel is not ..., although an occasional rock projecting into the concrete space was ... removed unless it came within 4 in of the inside finished surface of the ... In timbered ground the concrete was placed between the timbers and ... minimum distance of 4 in in front of them. The inverted siphons of the ... aqueduct are lined with concrete, ordinarily 2 ft thick, though solid

rock was permitted to project to within 10 in of the interior surface. C to the great hydrostatic head, reaching 700 ft, to which these linings are subjected, all timbering was removed before the concrete was placed; necessary, especially designed steel supports carried the roof while the crete was setting. In the Snake Creek tunnel a zone of swelling groun encountered which resisted all efforts to hold it in the ordinary way, the st est timbers obtainable being crushed in less than a month's time. A co lining reinforced with steel rails (Fig 21) was therefore introduced (46).

19. Driving Through Loose or Running Ground

Materials requiring special methods of support may be classified as follow

A. Rock which will probably stand, but under which the miners can work in safety, while ordinary timber sets and lagging are being erected.

B. Rock or other material which is certain to crumble and cause light unless promptly supported.

C. Soft material which requires immediate support and brings heavy p sure on lagging and timbers.

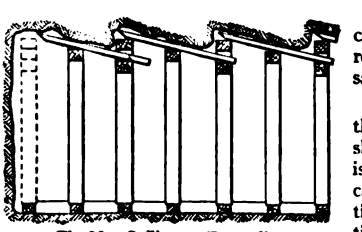

Fig 22. Spiling or Forepoling

D. "Running ground": from consistency of broken, muddy, slipp rock, down to semi-fluid mud, sil sand.

Class A. Headings driven un these conditions can be timbered shown in Fig 22. Each alternate p is slightly shorter than the others carries a double cap. This system timbers and driven lagging is sot times used also for material of Class but since each length of lagging cov two spaces and three caps, it is not recommended when driving under hea roof pressure. It is used primarily to protect the workmen, affording a ne

controlled and effective support, at the minimum expenditure of material and

—The terms "lagging," "forepoling" and "spiling," are used interchangeably about the United States, but "forepoling" is the usual designation abroad.

Class B. In this case the tail-block system shown in Fig 23 is satisfactory. If in common use, in nearly every gang of men will be some who have experience with it. A disadvantage is that a slight pressure on the forward end of the lagging pieces creates much friction between the tail block and the

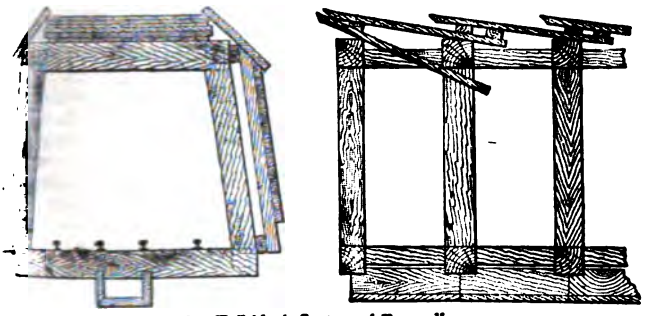

Fig 23. Tail-block System of Forepoling

so that driving the lagging may become difficult; but, when the ground is heavy and only light falls occur, this system is unequalled for cheapness and simplicity. In going through coarse, loose rock, where the jarring effect driving the spiling forward with a sledge increases the tendency to fall and the lagging may be forced forward by a screw jack, which, while slower than the hammer, is less apt to bring down loose material.

Removable tail-block. In many cases the removable tail-block system (Fig 24) possesses advantages over the preceding. When the spiling pieces are driven home, the wedges above the tail blocks are knocked out and the spiling allowed to rest on the auxiliary cap; the tail block is then removed and kept for use on the next set.

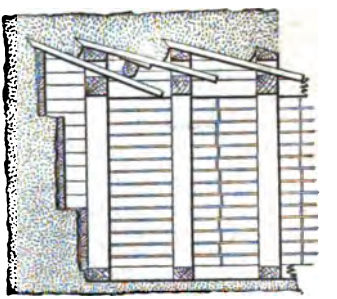

Fig 24. Forepoling with Removable Tail-block

Class C. For this kind of material a proper system of support becomes necessary. The commonest devices are the stationary and the swinging false sets.

The **stationary false set** consists of a set of timbers (Fig 25, *A*) placed midway between the permanent sets, to cover the distance through which the unsupported spiling has to carry the load. Where spiling is required for only a few sets, this system works well; but it possesses many disadvantages, and when a considerable distance must be driven through class C material, the swinging false set is preferable.

The swinging false set is shown in Fig 26, in connection with a thre arch cap for very heavy ground; it can be applied with even greater fac

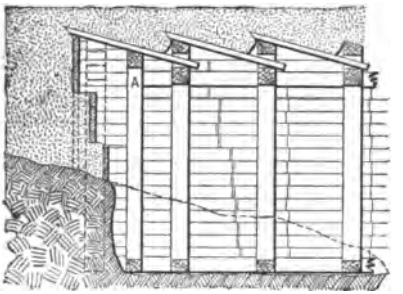

Fig 25. Forepoling with Stationary False Set

the ordinary horizonta There are no tail bloc does the spiling have driven across three sets bers, as in Fig 22. The coming on the front e the spiling is carried dire the swinging false set, a spiling can be driven wi less hammering than is re with the tail blocks. A cated in the longitudin tion, the posts of the sw false set rest and rotate sill of the permanent se when first erected occup position shown by the dotted lines. They carry a cap of heavy steel p which supports the front end of the spiles *a*. While driving, the only pr to be sustained is that of the rock immediately above and in front of *A;* wh with the tail-block system, a few pounds weight on the front end of a brings 4 or 5 times as much weight on its supports. As the spiling is d

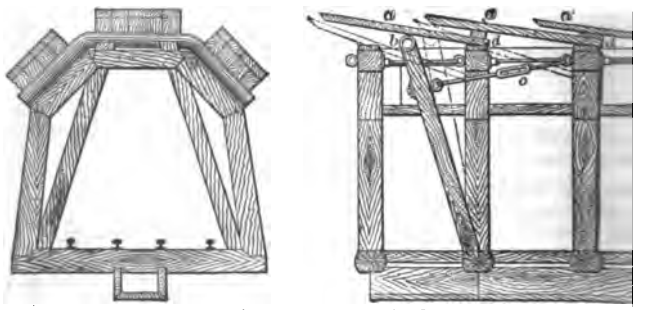

Fig 26. Swinging False Set

the turnbuckle *c* is slowly unscrewed, allowing the false set to fall forw until the spiles are nearly horizontal. When all the spiles have been d home, and the supporting block *d* placed under them, the turnbuckle is sla still farther, until the swinging set loosens. Then the hanging rods are unho from the eye-bolts and the false set is advanced to its next forward positi

In addition to the swinging sets and hangers, this system requires that the tin for at least 5 or 6 sets from the face shall be connected by tie rods, in much the manner as hanging bolts are used in shaft timbering. This, however, is an advan because, by screwing the timbers up tightly against the braces, they can be block position more easily and quickly. Also, the timbers are held in place so rigidly if hard ground is encountered in any part of the face, heavier charges of explosive safely be used than if the timbers were held in place only by blocks and wedges.

Class D. For driving any considerable distance through the difficult cla material, the shield and air-lock give satisfactory results as to speed, sa

economy of operation, in connection with railroad tunnels; but the high cost is rarely, if ever, justified for the narrow zones and small areas of mixed rock, or other bad ground, generally encountered in mining tunnels.

When the ground will stand for a short time in a nearly vertical face, the manner of driving lagging does not differ materially from that suited to classes B and C, except that the ground must be carefully and closely lagged, and the small corners between the vertical and horizontal lagging entirely covered by breast boards or "lacing," as shown in the cross-section, Fig 23.

Running ground. Plastic or semi-fluid material is difficult to hold back except with breast boards across the face (Fig 24). The head boards must be carefully blocked and advanced from the top downwards, never in the reverse direction. To prevent runs of thin mud from between the lagging or lacing boards, tough, wiry hay may be used as calking, a bale of it being kept at hand near the face. Working with breast boards in the face is a slow and difficult operation. As there is usually pressure from above as well as from the face, great care is necessary to prevent the boards from being forced inward, admitting an inrush of soft material. It is often necessary to tie the breast boards to one another and to the posts with pieces of inch boards and wire nails. For this kind of work, experience, skill, and constant care are demanded.

Boulders or rock in class D material. The difficulties of driving through ground designated as class D are greatly increased when boulders or masses of solid rock extend part way across the heading (Fig 25). The soft ground must be thoroughly lagged and breast-boarded from 6 in to 1 ft beyond the space necessary to erect the timber set, and the rock projecting into the tunnel is carefully broken with light charges so as not to disturb the breast boards or lagging.

When much water is encountered in a firm rock heading, it merely causes discomfort and inconvenience to the men. But, if heavy inflows of water occur in soft rock or running ground, quantities of sand or silt may be brought in, and if the lagging and breast-boarding are driven so close that the water is entirely shut off completely, the resultant pressure may become dangerous in the confined condition of the work. Sometimes the volume of water is so great that even in fairly hard rock, anything like a reasonable rate of progress is impossible. In such cases, it is usually cheaper, safer, and quicker to run a small lateral to tap the water and drain the face, thus facilitating the work of miners. When large volumes of water continue to enter the heading as it is advanced, it may be best to carry a lateral parallel to the main tunnel and keep its face somewhat in advance of the main heading, thus draining the water through a smaller opening, the alinement of which needs not be maintained with exactness. By this means the main heading is generally relieved of both the volume of water and the pressure accompanying it, and the cost of driving is reduced.

COSTS OF TUNNELING

The following data, showing the cost of driving a number of tunnels under different conditions, are as complete and accurate as could be secured. These data were in all cases obtained from persons in charge of the work, or who were in a position to know the actual costs, and may be taken as authentic. Accompanying the cost figures are schedules of the wages paid the different classes of labor and data as to the speed of advance.

Laramie-Poudre Tunnel (9, 13, 22, 27) 11 306 ft

	Cost per ft		
Superintendence and foreman	$1.50	Picks, shovels, and steel	
Drilling	4.47	Explosives	
Mucking and loading	4.92	Lamps and candles	
Tramming and dumping	4.63	Oil and waste	
Track and pipe	0.47	Blacksmith supplies	
Power house	0.35	Liability insurance	
Blacksmithing	0.84	Office supplies, telephone, and bookkeeping	
Repairs	0.47		
Bonus to workmen	1.75		
Maintenance, of buildings, and fuel	0.62	Permanent equipment (less approximately 10% average)	
Machinery repairs	0.12	Total	
Air drills and parts	1.33		

Permanent equipment included power plant, camp buildings and furnishings rails, cars, etc.

Wages: Drillers, $4.50; helpers, $4.00; muckers, $3.50; blacksmiths, $5.00; $4.50; dumpmen, $3.50.

Maximum progress in any calendar month: 653 ft, March, 1911. Average progress: 509 ft (for the 16 months when finished plant operated).

Special features: Inaccessibility; the tunnel was located about 60 miles fr nearest railroad siding, and the roads were mountainous and very steep in places

Elizabeth Lake Tunnel (3, 14, 16). In the following table the first states the cost per foot for driving the north heading 13 370 ft through granite, requiring 13 031 ft of timbering; the second column relates to the heading, 13 500 ft through medium to hard granite, requiring only 3 42 timbering:

	North heading	So hea
Drilling and blasting	$11.25	$14
Mucking and tramming	11.70	11
Engineering and superintendence	1.27	0
Drainage	0.45	0
Ventilation	0.22	0
Light and power	5.55	4
Timbering	8.48	2
Cost of shaft at sta 30 + 16	0.93	.....
Permanent equipment (full charge, no salvage — estimated)	3.70	3
	$43.55	$38

Wages: Drillers and helpers, $3.00; muckers, $2.50; blacksmiths, $4.00; h $2.50; motormen, $2.75; dumpmen, $2.50.

Maximum progress in any calendar month: 604 ft, April, 1910. Average m progress per heading: 350 ft.

Minion Tunnel, South Portal, May, 1909 to Sept, 1911, 5 515 ft

	Cost per ft		Cost per ft

†Includes candles, electric-light bulbs, shovels, picks, blacksmith's supplies and fuel, [illegible] mechanics' supplies.
‡Rates: Drillers, $3.50; helpers, $3.00; muckers, $2.75; blacksmiths, $4.00; helpers, [illegible] motormen, $2.75; dumpmen, $2.50; power engineers, $2.75.
§Maximum progress in any calendar month: 414 ft, Feb, 1911. Average monthly [illegible] 110 ft.

Newhouse Tunnel (19, 20, 50)

	Jan to Aug, 1909, 2 233 ft	Sept to Dec, 1909, 1 098 ft	April to Aug, 1910, 693 ft
[illegible]	$6.72	$6.98	$11.73
[illegible]ives	4.15	3.52	4.57
[illegible] and caps	0.39	0.36	0.44
[illegible]moval of broken rock	1.49	1.47	2.22
[illegible]	1.99	2.16	2.82
[illegible]timbing	1.57	2.61	2.00
[illegible] drills, repairs, and steel	1.50	2.74	2.86
[illegible]ment, ties, rails, pipe, etc.	1.74	1.78	2.19
[illegible]	0.79	0.80	1.85
	$20.34	$22.42	$30.68

*Rates: Drillers, $4.00 to $4.50; helpers, $3.25 to $4.00; muckers, $3.50; motormen, [illegible] dumpmen, $3.00; blacksmiths, $3.50 to $4.50; helpers, $3.00.

Stilwell Tunnel

Year—	Footage	Cost per ft
1900–01	12	$23.88
1901–02	490	22.98
1902–03	377	27.94
1903–04	702	21.69
1904–05	1 077	21.19
1905–06	292	30.37
Average for	2 950 ft	$23.38

*These costs include all labor, supplies, repairs, powder, fuse, caps, candles, tools, [illegible] and general expenses; also total value of electric-drill plant with which tunnel [illegible]ed and total value of air-drill plant which succeeded it, together with buildings, [illegible] and ventilator, with no credit for salvage on any permanent equipment. The [illegible] dated from Sept 30. The tunnel was driven in 1901–03 with electric drills; [illegible] cost for 1905–06 was due to station cutting, where the tunnel was double size.
†Rates: Drillers, $4.50; helpers, $4.00; muckers and trammers, $3.50; blacksmiths, $4.50.
‡Maximum progress in any calendar month: 170 ft, Aug, 1904. Average monthly [illegible] 130 ft (last 10 months).

Rawley Tunnel, 6 235 ft (59)

	Cost per ft		Co
Drilling and firing	$5.25	General expenses	$1
Mucking	2.16	Permanent plant	3
Tramming	1.13	Timbering (1 618 ft)	1
Track and pipe	0.44	Boarding house, debit balance	0
Miscellaneous underground expenses	1.44	Total	$20
Power plant	2.50	Credit salvage on permanent plant	1
Blacksmithing	0.73	Net cost	$19
Miscellaneous surface work	0.83		

Drilling and firing include labor, powder, fuse, caps, supplies, and repairs. M tramming, and track and pipe include labor and supplies. Miscellaneous under expenses include wages of foremen, underground telephone, etc. Power plant i labor, supplies, and fuel. Blacksmithing and miscellaneous surface work includ and supplies. General expenses include salaries, office supplies, telephone, etc. nent plant includes machinery and buildings, with labor of installation, steel rail manent supplies, and repairs. Timbering includes labor and supplies.

The salvage on the permanent equipment was approximately 50% on salable a such as machinery, rails, cars, etc.

Wages: Drillers, $4.50; helpers, $3.75; muckers, $3.50; blacksmiths, $4.50; d $4.50; power engineers, $4.00.

Maximum progress in any calendar month: 585 ft, July, 1912. Average m progress: approximately 350 ft.

Roosevelt Tunnel (14, 18, 20)

Total cost of portal heading		$111 980.06
Contractor's percentage		11 404.88
Cost of shaft headings		262 126.55
Total cost		$385 511.49
Distance driven	14 167 ft	
Average cost per ft		$27.27

Note. — Numbers in parentheses in text refer to Bibliography at end of this section.

1. Cross-section of Shafts

Cross-section may be rectangular, round, or elliptical. Choice depends on ... material, character of ground, and local practice. RECTANGULAR section ... where timber is cheap, and volume of water moderate. It requires ... excavation for given hoisting area, is best adapted for aver conditions in ... rock and is most widely used. CIRCULAR section is adaptable to ... or metal lining, and is strongest against heavy ground or water press. ... less surface and hence less resistance to passage of air, while the ... areas about hoisting compartments furnish required ventilating, pipe, ... space without providing special compartment. ELLIPTICAL section ... of strength of cylindrical form and space economy of the rectangular. ... to timber and to keep plumb when sinking.

2. Division into Compartments

Rectangular shafts with compartments side by side are most conve timbering (Fig 1). With the oblong section, width of collar between th cut holes may be made large, resulting omy of explosive (Art 7). In heavy if long dimension of the compartments the shaft, the dividers are brought c gether and are better able to withst pressure. In steeply dipping strata, t walls are best supported, and safety c increased, by laying out the shaft with its short axis parallel to strik strata. If such location is impossible, special precautions must be taker the long wedges of rock from which support has been removed.

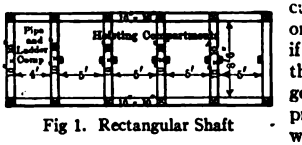

Fig 1. Rectangular Shaft

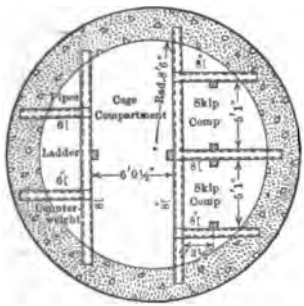

Fig 2. Plan of Cylindrical Shaft

In firm ground, where structural st lining is not the determining factor, sl be made to suit operating conditions. shafts, or those having a width of 2 ments, do not permit convenient arra of stations; landings are separated a plicated track arrangements are require nect them; and miners are in dang

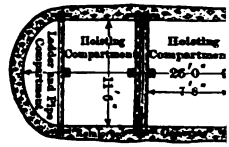

Fig 3. Plan Modified Ellipti

crossing between compartments. The Forman shaft (Comstock lode) was sunl form of an *L*, 3 compartments being in line with a large pump and service comp at one end; it proved unsatisfactory; unequal pressures caused timbers to crac and repairs were costly.

Cylindrical and elliptical shafts, the shape of which assures str strength, may have compartments arranged as operating conditions d Fig 2 and 3 show typical plans.

3. Size of Shafts

Cross-sectional dimensions are influenced by: purpose; tonnage hoisted; quantity of timber and supplies to be lowered; number of under employes; amount of water to be raised; method of hoisting (cage or skip); acter of ground; and questions of ventilation, cost, and operating charges minimum cost per foot of depth, a shaft has a cross-section of approx 4 or ft; smaller sections cost more, due to cramped positions of miners and in to drill holes to get best effect from explosive. When a shaft larger th minimum is required, size may be determined from above factors.

Prospect shafts are frequently of minimum size, and may have but 1 compar which serves for both hoisting and ladderway.

Air shafts may have 1 or 2 compartments, the second being a small ladderwa fireproof curtain wall. Single-compartment shafts in solid rock are frequently cyli and left unlined. Most economical size for air shaft, or air compartment of working may be determined by balancing annual charges of different cross-sectional areas cost of forcing the required volume of air through these areas.

Sinking shafts are usually divided into 2 or more compartments, one of which contains ladders, pipes, and wires. Shafts used exclusively for hoisting sometimes have no ladderway; all chance of injury to human life being avoided, hoisting is governed accordingly and is frequently automatic.

Size of compartments. Minimum size is determined by cage needed to accommodate the mine car in use (Sec 11, Art 3; Sec 12, Art 22–24); or, for skip hoists, the volume of ore to be hoisted per trip is the governing factor (Sec 12, Art 2). In American metal mining, hoisting ¾ to ⅞-ton cars, size of hoisting compartments, inside of timbers, varies from 4 by 5 to 5 by 7 ft; or for a 3-compartment shaft, a net clear section of approx 4.5 to 6 by 12 to 18 ft. In coal mining the cars are larger and compartments 6 by 10 or 7.5 by 12 ft are common.

Two-compartment shaft (one hoisting compartment), equipped with an underground hoist, was common in the early days of American metal mining. This is uneconomical of power, and is to be recommended only for shallow mines of small production.

Three-compartment shaft, with balanced hoisting in 2 compartments, is favored for economy, and is therefore usual for mines of moderate production.

Lowering men and materials in a 3-compartment shaft, hoisting 24 hr per day, leaves from 50 to 70% of total time available for ore carrying; this percentage may be increased by using a small cage compartment in manway (Fig 4), in which can be handled supplies and mine officials, and when the shaft is used for sinking. Such a compartment is unsuited for handling miners when changing shift and is awkward for handling timbers. Its cage is generally operated by a small auxiliary, unbalanced hoist.

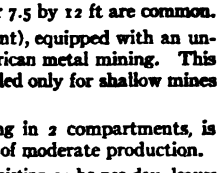

Fig 4. Shaft with Service or Sinking Compartment

Four-compartment shaft usually has 2 ore-hoisting compartments, a service compartment, and a pipe and ladderway. The ore-hoisting compartments are relieved of other work; men and supplies are handled promptly in the service compartment, which in emergency may assist in hoisting ore.

A small portion of manway is sometimes set aside for a counterweight, enabling the hoist to operate in balance. In a 4-compartment shaft, the ore-hoisting compartments are often equipped with skips, and the service compartment with a cage. Its firm (Fig 21), so that timber trucks can be run onto the cage without standing the timbers. In very wet shafts, to facilitate handling the pumps, it may be desirable to make a part of the pipe and ladderway as a small cage compartment.

Five-compartment shaft, with 4 ore-hoisting compartments and a manway, has advantage of balanced hoisting at all times. Two compartments are generally from 40 to 60% of the time for service work.

Conditions of great depth, large production, or a combination of both, involve practical questions of hoisting and ventilation which make necessary large shafts with numerous compartments.

The northeast shaft of the Government Gold Mining Areas, Witwatersrand, has 7 compartments, rock section, 45 by 10 ft. The 7-compartment Wolhuter shaft, Rand, has a section 46 by 9 ft. In the Lake Superior iron district, U S, 13 by 21-ft shafts are in use. U S colliery shafts range in rock section up to 14 by 50 ft.

Rock section should be cut of sufficient size to allow 3 or 4 in outside of timbers, for lagging and wedging. Rock removed in excess of this involves needless expense in breaking, mucking, and timbering.

4. Sinking Plant

Temporary plant used for sinking commonly consists of following equipment. Hoisting apparatus: windlass, whim, or engine, together with hoisting rope, and

buckets or skips. Support for sheave: tripod, derrick, or headframe. ment for removing water: bailing tanks, steam, or electric sinkin Boiler plant. Air compressor, if machine drills are used.

Windlass and whim (Sec 12) are often used in starting a shaft and in sinkir surface soil before the power hoist is installed. Amount of water influences which their use is practicable; for depths over 20 to 30 ft their application to new work in remote regions, or where mechanical power is not available.

Sinking engines should be strongly built, of duplex type; many pend on their reliability. For depths to say 500 ft, and hoisting with bucket (Sec 12, Art 21), a friction-gear engine of 12 to 30 rated hp is a pending on size of shaft. After depth of approx 500 ft has been reached engine, preferably of reversing type, is commonly employed.

Tripod made of timbers bolted together at top, from which point sheave is s forms a simple sinking headframe. A second sheave is sometimes fastened t of tripod leg nearest the hoist, to lead rope off horizontally.

Stiff-leg derrick is often used for sinking through surface soil; it does not exer on ground immediately surrounding shaft, nor interfere with placing timbering o of permanent shaft collar. Donaldson (2) recommends for colliery shafts a der 40-ft boom and 30-ft mast of 12 by 12-in timber. Where derrick is used for s depths of 100 ft or more, provision should be made to prevent it from swinging wh is in the shaft.

Sinking headframe design is the same in principle as that of operat (Sec 12). It is smaller; usually has one sheave; and the distance sheave and crosshead in the dumping position is small. Sinking he should embody features for dumping buckets or skips; for protecting w on the surface and in the shaft from falling pieces of rock while dumpi for minimizing work of topmen, in dumping buckets and removing brok A contractor's sinking frame should be so designed as to be portabl erected and dismantled.

If conditions permit erection of the permanent hoisting plant and headframe for expense due to inefficient engine and duplication of equipment may be avoided. temporary plant is necessary, it should be so placed that the permanent plant erected in its proper location without interfering with sinking. In some cases, th hoist has been placed opposite the service compartment and later used for its o

Water up to approx 1 000 gal per hr may be hoisted, much of it filling broken rock in the buckets; for greater quantity sinking pumps are n (Sec 40, Table 11). For given character of rock, cost and speed of sha ing vary directly with increase of water.

Spring Mines vertical shaft, on the Rand (41), was sunk through heavily water strata. Size, rock section, 42 by 9 ft. Labor per shift, 70 natives, 1 white foren white assistant; 3 8-hr shifts per day. Cost per ft of shaft, $238.35. Sinki divided into 3 periods. 1. From time of striking water to installation of pump 2. From installation of station to installation of permanent pumping plant. 3 installation of permanent pumps.

	Period 1	Period 2	Peri
Depth beginning, ft	459	650	1 1
Depth ending, ft	650	1 142	2 8
Depth sunk, ft	191	492	1 6
Aver speed per month, ft	27.3	70.3	1
Water, gal per min	1 389	1 199	.....

Questions of steam economy in design of boiler plant must be subservi other considerations, particularly in a shaft where a sudden flow of water m encountered and pumps drowned if sufficient steam is not available.

...st of contractor's new sinking plant for a 500-ft shaft, making 30 to 40 gal of water ... is given by Donaldson (2) as follows:

...sting engine	$1 000	2 buckets	$150
...0-hp boilers and setting	1 800	Rope	150
...pe and accessories	500	Buildings	500
...0-hp feed-water heater	300	Dump cars and rails	300
...ir compressor	1 750	Electric lighting plant, 10 kw.	750
...ls and steel	1 000	2 sinking pumps	500
...ar and clamps	100	Small tools and sundries	500
...	400	Total	$10 200
...frame	500		

...st of erecting and dismantling plant, $1 000 to $2 000.

5. Organization

...re are two general systems of shaft-sinking organization. In one, the ...e men drill and blast the round, and broken rock is loaded by lower-... men. Efficient management is needed to prevent miners and muckers ...ering; when properly handled, this system is generally the cheaper per ft of ... The other system uses the men as drillers or muckers as occasion demands. ... first system both crews may work together in the shaft, or independently ...arate shifts. In the latter case, the bottom is carried in benches, and im...tely on going down all hands clear enough space for drills to begin work.

...sinking the No 5 Tamarack shaft, Michigan copper district, the cut and one side ...drilled and blasted in advance of the other side. Drillers' shift was timed to begin ...ddle of the muckers' shift. Muckers first cleared the side which had not been ...d and made it ready for the machine men, who then drilled and blasted before the ...d of the next shift of muckers. Drillers and shovelers each worked 2 shifts per 24 hr ...minimum amount of interference.

...k Oak shaft, Soulsbyville, Cal, was sunk with hammer drills. One crew drilled ...ire round of holes, and blasted and mucked the inner row of cut holes, in one ... During the two succeeding shifts, remainder of the ground was mucked and shaft ...d down ready for the drillers.

...e of the best machine-sinking records on the Rand was made at the Village Deep, ...g 3 8-hr shifts per day. The holes drilled during one shift broke ground for the ...g 2 shifts of muckers. It was often necessary to load and blast a round a second ...n a third time, the bottom being cleaned between blasts. This made necessary the ...ce of machine men or their equals in intelligence between regular drilling shifts for ...g, charging and firing the holes. Sometimes holes are blasted in relays, the broken ...ing removed after each blast.

...l men in the shaft drill or muck as needed, each shift can pick up the work ...less of the stage at which the last one left it. This system, operating 3 ... per day, makes for speed, with slightly increased cost per ft of shaft; but ...ives the use of experienced drill runners to do muckers' work.

...ection No 3, 55° inclined shaft of the Canadian Copper Co, the record for part of ... given in Table 1, was sunk by using 12 3½-in piston drills mounted on 6 columns, ... on a machine. Same crew did the drilling, shoveling, or timbering, as required, ...ing 3 8-hr shifts per day. They received a bonus equal to 1% of their wages for every ... over 100 ft per month. Hoisting was done in skips by a 2-drum geared electric hoist. ...er was 40% Forcite, fired electrically by delay-action fuses. Little timber was re... except for skip rails. Size of shaft is 35 by 9 ft, with 5 compartments each 6 ft 6 in ... 6 in.

...e features of the hammer drill which make it possible to take advantage ...e peculiarities of the face tend at the same time to minimize the regularity ...r work, and it is usual to find the same men drilling or mucking, as required.

...sbury shaft, Newport mine, Ironwood, Mich (3) during the 9 months ending Dec 1, ... was sunk at the aver rate of 185 ft per month, using 12 Jackhamer drills with same 12 ...lling and mucking.

a. Shaft 206 ft deep, Aug 1, 1915. *b*. S

Where shafts are sunk by hand no attempt is usually made to distingui tween drillers and muckers. Drilling commences when the last bucket of h rock has been hoisted, and men return to bottom as soon as the smoke has cl

Record sinking on the Rand has been done by hand (Kafir labor). Each shift o down loaded rock broken by preceding blast; the next round was then drilled and l at end of shift. Three rounds were drilled, blasted and mucked per 24 hr. As mar are employed in the shaft as can be crowded into the space. At the State shaft, 45 ft, 82 Kafirs were used per shift. In very deep shafts, air is blown down so that wh last hole is fired the next shift starts down, meeting the ascending fumes; the ti quired to pass through the foul-air zone is so short that no bad effects result.

Delays may be classed as follows: removing drills and other equipment shaft bottom preparatory to blasting; clearing bottom of smoke; clearing walls and timbers of loose pieces of rock and securing bad ground after bla lowering timbers, which may be put in place during drilling.

Where pumps are in use the suction is removed from bottom and pump stopped blasting; in very wet shafts, this may result in several feet of water accumulating time of blast, which acts as a cushion to protect timber and pumps, and absorbs m the powder smoke. This must be pumped or bailed miners can go down.

Table 2. Bonus Paid White Employes, Village Deep Shaft (36)

Advance per month, ft	Bonus per ft	Division of bonus	
		Occupation	%
60 to 70	$ 9.73	Machinemen	60
70 to 80	14.59	Timbermen.....	10
80 to 90	19.45	Boss shovelers	8
90 to 100	34.04	Topmen.....	4
over 100	48.63	Miscellaneous.....	12

Rock section of shaft, 28 by 8 ft.

By operating 2 shifts pe much of the above work be done between shifts; is also time to make up fo usual delays. With 3 shif such opportunity exists; is increased, but at a sli greater cost per ft than w shifts.

Bonus system of pa workmen lends itself readily to shaft sinking, and in many cases has increased s and reduced cost per ft. Bonus is paid either as a percentage of wages for foot in excess of a given standard, or the company may allow a lump sum ft to be apportioned among workers, as at Village Deep, Rand (Table 2).

Feb 24, 1916, to cut station at 14th level.

Safety precautions (4). No other operations should be carried on, nor tools material raised or lowered to or from other points in the shaft, while men are in bottom, unless they are protected from falling material by a well constructed TIMBER PENTICE extending over nearly the entire area of shaft, with openings for passage of buckets. In deepening a working shaft, an ROCK PENTICE should be left, or timber bulkhead built before sinking begins.

Trap doors, normally in closed position, should be provided at collar to cover shaft with additional set of trap doors when dump point is above collar, to prevent of falling rock breaking through the collar doors. At Woodbury shaft (3) in the shaft was provided with a felt hat stiffened with resin and shellac. These hard and capable of resisting severe blows from fragments of falling rock.

or skips should stop at least 15 ft above bottom, until rung down by one of Ladderways should be provided to within such distance from bottom as will injury to them from blasting; from end of these, chain, wire rope or wooden ex- ladders, should be provided to reach bottom of shaft. This assures safety of men failure of hoisting engine, fire or sudden inrush of water.

electric hoists are used, electric lights in shaft bottom advise sinkers of interrup- current. In some districts the law provides that all blasting in shaft sinking shall by electricity.

6. Drilling

Drills used in shaft sinking are: hand-churn, single or double hammer, and or hammer machine drills.

Hand-churn drill in the hands of energetic workmen may be used with ad- in soft rock. Hole is usually started with hammer and drill. More must be taken in shaping the bit than for hammer drilling, and a low temper able.

Hand hammer drilling is best applicable with low-priced unskilled labor. number of comparatively shallow holes, approx 3 to 4 ft, are drilled per Advantages are:

Greater speed, especially where many drillers may be packed into the shaft bottom, Rand, where the world's records in speed have been attained. Such speeds can approached in hand drilling with high-priced labor, as the men will not tolerate such conditions. At the State shaft, Witwatersrand, 45 by 10 ft, 82 Kafir drillers

were employed per shift, giving a max advance of 233 ft per month. (*b*) In placing full advantage may be taken of all peculiarities of rock in shaft bottom, resulting in economy. (*c*) Lighter charges are used in shallow holes, compared with machin ing, with less, shatte shaft walls, and timbering. Shaft sec confined more exactly sired size, and timbe facilitated. (*d*) By a ing bottom in a se benches, the burden hole becomes less, wit omy of powder. In Rand shafts, the top is sometimes 40 ft abo sump. This method feres somewhat with ing, especially if onl hoist is in operation. bench system may also be used with machine drilling, but is not so advantageous hand work. (*e*) None of the delays incident to machine drilling, as for setting up and hoisting them out before blasting.

Table 3. Comparison of Hand and Machine Drilling, Goldfield, Nev (40)

	Hand	Machine
Men per shift	5	6
Shifts per day	3 8-hr	3 8-hr
Aver advance per day, ft	3.81	4.2
Powder per ft advance, lb	8.0	11.68
Powder per ton rock broken, lb	0.93	1.25
% of total time:		
Drilling and blasting	37.6	29.2
Mucking	40.4	45.5
Timbering	22.0	25.3

Comparison of hand and machine drilling at Goldfield, Nev. A 7 by 16-ft v shaft was sunk from 470 to 700 ft by hand, 60% of the drilling being done by churn and 40% by single-hand work; from 700 to 1 200 ft, 4 2¾-in Ingersoll-Rand ma were used. Rock medium hard.

Table 4. Comparison of Powder Consumption, Hand and Machine-dri Holes, Rand

Wolhuter	46 by 9	95		2.55

Hammer drills (Sec 15), which work best on down-holes, are well adapte shaft sinking. They partake of the advantages of hand work, without nece

skilled labor willing to be packed in the shaft bottom. They are best ... for vertical or steeply inclined shafts, where fractures or cleavages are ... in strata, since in this case the placing of each hole with regard to local ... of the rock is of most importance.

... drills have also been used successfully in ground where each successive round ... in practically the same manner. The advantage of the hammer over the re... drill is not in better drilling speed, but in the shorter time for setting up, tear... shifting from one set-up to another.

... Black Oak shaft, Soulsbyville, Cal (5), sinking was carried to the 1 600-ft level ... reciprocating drills, one miner and a helper on each machine. Below the 1 600-... hammer drills were substituted for the reciprocating machines, with the same ... of men in the shaft. The result was a 25% increase in rate of advance and a ... air.

... shaft (45), near Ducktown Tenn, rock section 7 by 14 ft, penetrated very hard ... schist. By substituting 6 Jackhamers for 4 reciprocating drills, an advance ... per month was made for 315 ft; about double the best previous record. (For ... details, see Art 21.)

Reciprocating drills (Sec 15) have general application for heavy shaft work, ... from question of speed compete successfully with other drills, and ... Rand even with hand work, though the conditions there for manual labor ... In rectangular shafts, reciprocating drills are usually mounted on ... bars (Sec 15), placed across the shorter dimension of the shaft. From 1 to ... drills are mounted on each bar.

... large American colliery shafts, drills are mounted on tripods; but the tripod is ... and more cumbersome than the shaft bar, and altogether the practice has little ... it in a rectangular shaft. With circular or elliptical shafts, the use of shaft ... difficult and tripods are the rule. In Europe several types of sinking frames ... devised for circular shafts, on which the drills may be so mounted as to com... entire cross-section. The frame with drills attached is raised to the surface ... blasting (6, 7).

7. Depth of Drill Holes

Depth of hole (Sec 6, Art 7) is a function of shape and size of shaft and char... rock. The deeper the cut holes the greater the width of collar possible ... the two opposite rows, and the less the number of breaking-out holes ... Usual depth of HAND-DRILLED HOLES is from 2 to 5 ft. With RECIP... DRILLS, the maximum depth consistent with powder economy is ad... as this reduces the percentage of time lost in setting up and taking down ... holes, and in raising and lowering the drills before and after ... The proper depth of hole should be determined by a series of experi... any particular rock and other conditions. In absence of other data, ... may be assumed equal to one-half, or in soft ground three-fourths, the ... the shaft. In some districts, the practice has been to drill long holes ... 2 or even 3 times; this involves waste of explosive unless, before charg... hole is partly filled with sand or other easily removable material.

... to 10 or 12-ft holes, or deeper, is the excessive weight of steel necessary to ... a hole at a size large enough for a sufficient charge of powder. Long steel is ... to handle in sinking buckets. The drill steel for HAMMER DRILLS being ... that for reciprocating machines, the limit of length of hole which it is possible ... still have a cross-section large enough to hold enough powder to break well, ... the way the steel holds its gage.

... Woodbury shaft, Ironwood, Mich, 10-ft holes were possible, in soft slates, while ... and quartzites, starting with a 2¼-in bit, 8 ft was the max depth of hole.

... hard rock at the Gordon shaft, near Ducktown, Tenn, reciprocating machines ... 7-ft holes and made approx 5 ft advance per round. Hammer drills put down ... holes, and made approx 2 ft advance per round.

8. Location of Drill Holes

Drill-hole location in sinking is governed by fact that only one free exposed, and that to obtain max efficiency from charge 2 free faces are nec (Sec 5, Art 5). One or more key or cut holes are drilled at an angle to t face, and blasted in advance of the other holes, which are placed to take tage of new face formed when the cut is blasted. The cut is usually drilled middle of the shaft section, though in large shafts some engineers prefer it towards one end, retreating towards the opposite end in blasting, and each row of holes in series. This arrangement tends to throw the broke to one end of the shaft so that the opposite end may be speedily cleared machines to begin work while mucking is in progress. Local conditions, ding planes, reentrant angles, position of hoisting compartment, etc, som influence position of cut. The max blasting force is developed if oppos holes meet at the bottom and are fired simultaneously. The obtuse an tween opposite cut holes should be as great as conditions permit (Sec 6,

Hand-drilled holes are usually shorter and more numerous than machine-drilled; they are placed with care to take advantage of bedding planes, cracks and shape of face, not with especial regard to symmetry of arrangement. The cut is sometimes carried well in advance of the other holes, which recede towards the shaft ends in a series of benches.

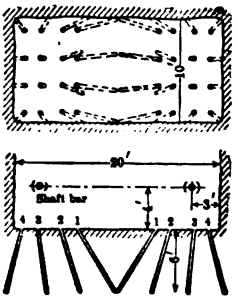

Fig 5. "V," Center or Wedge Cut for Shaft Sinking

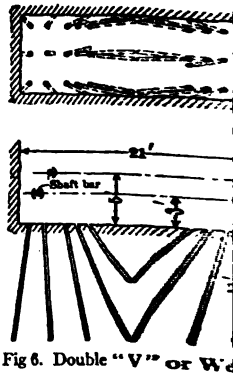

Fig 6. Double "V" or W

Machine-drilled holes are placed and pointed in accordance with a system designed to give desired results increased powder consumption. A symmetrical a ment facilitates the operation of the drills, and the max number of holes to be drilled from each of the shaft bar (Sec 6, Art 6).

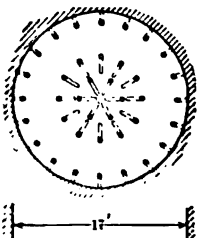

Fig 7. Pyramid Cut for Circular Shaft

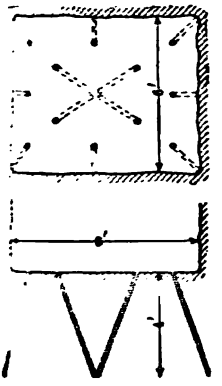
"V," center or wedge cut is most commonly u comprises a number of pairs of holes inclined towa other from opposite sides of the short center line shaft, their bottoms being close together or preferabl ing. Fig 5 shows a simple "V" cut, with positions bar for drilling. Holes in lines 1 comprise the cut blasted first, holes in lines 2, 3, and 4 being fired in su Fig 6 shows 4 rows of holes for a deep cut. In soft it is sometimes sufficient to drill only one line of c on each side, or, if the second line is used, to drill th half the depth of corresponding hole on opposite side

Pyramid cut is rarely used except in circular sh consists of center holes surrounded by others more concentric and so inclined as to form a sump at c shaft. Fig 7 shows arrangement of holes in a Catskill Aqueduct shaft. Pyramid been applied to rectangular shafts in the Joplin, Mo, district (Fig 8). Cut h

...st, followed by side and corner holes in the order named. In small shafts, ...ay be used to blast the sump.



Pyramid Cut for Rectangular Shaft

Center and wedge cuts are sometimes combined by pointing the holes nearest the center of

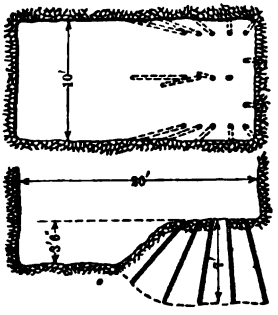


Fig 9. Bench or Stope Cut

... to take out a small sump; the remaining holes are then arranged in ordinary ... fashion.

Bench or stope cut is sometimes used in tight ground (Fig 9). The cut is alternated ... side of the shaft to the other. There are always 2 more ... faces, thus increasing the efficiency of blasting. This ... to project the broken rock towards the opposite end of ... instead of directly upwards as do the wedge and center ... there is less delay in setting up drills, and risk of ... to timbering and pumps is reduced; also one end of shaft ... lower than the other, facilitating mucking and drainage.

Fig 10. Bottom Cut for Flat Inclined Shaft

Bottom cut, similar to that used in tunnel work (Sec 6, Art 6), ...times useful for flat, inclined shafts (Fig 10).

8. Explosives, Blasting, and Mucking

Explosives (see Sec 4 for full discussion). 40% gelatine dynamite is generally ... sinking in American practice, where holes are drilled by hand or recipro-

Table 6. Consumption of Explosive in Shaft Sinking

Shaft	Size of shaft, ft	Explosive used (dynam)		Rock
		Strength, %	Lb per cu yd	
...s coal, Pa	13 by 26	40	1.26	Shale, slate
...	14 by 18	40	1.12	Sandstone
...educt	10 by 22	60	2.10	Quartz conglom
...	17 diam	60	0.94	Shale
..., Cal	18 by 11	40	4.6	Schist, slate (*a*)
...com	12 by 24	50	1.3	Shale
... Nev	4 by 8	40	3.0	Andesite
Eagle, Cal	7 by 12	40	1.3	" (*b*)
...nd Jack No 2, Rand	7.5 by 21	93 (*c*)	2.3	Quartzite
... East, Rand	.....	93 (*c*)	1.05	" (*b*)

(*a*) Inclined 60°. (*b*) Hand drilled. (*c*) Blasting gelatine.

cating drills. In some cases, 60% dynamite is used in the cut holes and bottom of others. The relatively small, deep hole drilled by hammer dr led to the use of stronger dynamites; 60 or 80% gelatine is common, w hard ground 2 or more sticks of "100% gelatine" are sometimes placed bottoms of holes. In Rand shafts, 93% blasting gelatine is common. The amount of charge should be determined by experiment.

Mucking is facilitated if the major portion of the rock is broken in pieces weighi 20 to 200 lb, which can be loaded by hand. Shoveling in a shaft bottom is diffic takes more time than handling an equal quantity of rock in large pieces. Where of the shaft is drilled and mucked in advance of the other, shoveling is facilit covering the bottom, opposite the side to be blasted, with steel plates; the blast throw the broken rock onto the plates.

Blasting may be done with ordinary cap and fuse, timed to give succe shots, or by electricity. By the latter method the entire round may be once, or the different series of holes timed to detonate as desired by use c electric blasting caps or electric delay-fuse igniters.

In some districts the law requires electric blasting in sinking. Timbering carri to the bottom is liable to injury from concussion and rock bombardment caused simultaneous electrical detonation of an entire round of holes; this danger is less use of delay devices, or by firing the series of holes in succession.

In using ordinary fuse and caps, many engineers advise doubling the fuse, 2 de with equal lengths of fuse being inserted in each hole. If the fuse is wound arou erly placed nails or hooks and cut at only one of them, with caps crimped on bo the mark made by the other nail or hook will show the place where the fuse is to be spit at blasting time.

Where the shot-firers begin spitting at each end of the shaft and work tow middle, they need not walk over lighted fuse, possibly stepping on one and puttin The men are also nearer the bucket at the finish. This method involves cutting for each series of holes at different lengths, so that the cut holes which are general center will explode first. When spitting begins at the center, all fuse may be cut length and proper order of firing naturally follows; and if the entire round is through any cause, the cut holes and those nearest to them are sure to explode. keeper fuse, cut so that it will burn out about 2 min before the first charge is explode, serves as a warning that it is time to get to safety. In wet shafts on th fuse is spit by torch, or "Cheesa stick," made by splitting blasting gelatin, wra around a pine stick about 18 in long and covering with clay. The fumes give readily absorbed by the water without any bad effect. In part of the Woodbu (3), the ends of the fuse were lighted by being placed in a cardboard box containi powder which was ignited by an electric fuse. Great care was exercised and end kept dry. Considerable smoke resulted from burning black powder and long lengths

Mucking, or loading broken rock into hoisting conveyance, occupie 50% of shaft-sinking time. Number of men employed depends on me organization, size of shaft, and number and type of containers for hoisti For VERTICAL SHAFTS, a bucket or skip is sometimes suspended from bo sinking cage, which is provided with long guide shoes to permit lowerin the last set of timber. In other cases, sinking crossheads (Sec 12, Art used to prevent bucket from swinging. On the Rand, skips have been us guide shoes long enough to engage the lower end of guides when the sk is on shaft bottom; they are considered safer than buckets. For IN SHAFTS, buckets sliding on skids, or suspended from a carriage runnin cableway, and skips running on regular track, are in general use. Ten track, capable of being raised on blasting, is provided to reach from end bering to shaft bottom.

Empty bucket should always be available at bottom to render muckers inde of irregularities and delays. In large shafts, where more shovelers are employ can crowd around one bucket or skip, two compartments are sometimes used for

10. Ventilation (See also Sec 14)

...e sinking, enough air must be delivered at shaft bottom to remove powder ... and rock dust, and to enable sinkers to work in reasonably pure atmosphere.

Natural ventilation, set up automatically, may serve to great depths; in ... ases, **mechanical** ventilation must be adopted at the outset. Some of the ... governing natural ventilation are, character and temp of surface atmos. ... f strata penetrated, and amount of water falling in shaft.

Natural ventilation (Sec 14, Art 10) may be aided in several ways. If a small portion of shaft area is partitioned off by a brattice (Sec 14, Art 6), and this compartment ... up into the headframe by a chimney, difference of air head will cause circulation. ... steam sinking pumps are used, and steam pipes carried in a separate compartment, ... is usually sufficient to establish a rising current; a steam jet directed upward ... shaft bottom will accomplish same result. It often happens that, even with no ... the space around the steam pipes is upcast while the opposite side is downcast.

Fan or blower on surface, connected to a wooden or sheet-iron pipe 12 to 18 in diam, ... close to shaft bottom, may be used to force down fresh or exhaust foul air. It is ... satisfactory to use a fan to exhaust blasting fumes promptly; the fan is then ... to supply fresh air. If the pipe or chimney be of wood, the boards should be ... and painted to reduce leakage.

... compressed-air drills are used, the exhaust will generally remove dust and pre... air from becoming vitiated. Powder smoke is ... out by opening the air valve at the bottom ... Spraying water down the shaft facili... powder smoke.

11. Sinking in a Working Shaft

... shafts are frequently deepened while ... mining operations are being carried on ... Sinkers should be protected from falling ... by a rock pentice (Fig 11); or by a ... timber bulkhead, which is sometimes loaded ... or 15 ft of waste rock.

... are two general methods: (*a*) rock is ... direct to surface from shaft bottom ... special sinking compartment; (*b*) rock ... to the lowermost working level, by ... electric or compressed-air hoist, whence ... to the surface by regular hoisting ...

The rock pentice may be left across ... shaft area, in which case a short incline ... sunk from the level above before the ... widened to full section. If the pentice ... across bottom of hoisting compartments ... small opening may be cut in line with the ladderway, through which ... carried on (Fig 11).

Fig 11. Sinking Under Rock Pentice

12. Shaft Raising

... are sometimes raised instead of sunk, where an additional opening is ... a working mine. A raise is made on the center line of the proposed ... a cross-section just large enough for good delivery of the broken rock ... provide room for drilling. Where speed is an object, several points of ... may be opened by driving drifts from the mine levels to intersect the line ... When the different sections have been connected, the raise is ... out to the desired cross-section, thus eliminating any slight errors of ... If work is to be done in one lift, the raise is sometimes carried at ... section.

Shaft raising is faster and cheaper than sinking, no shoveling nor pumping bein essary. Expense of tramming rock to main hoisting shaft must be taken into ac but hoisting itself is cheaper, due to greater efficiency of the regular plant as con with a small sinking hoist. The broken rock may sometimes be used undergro stope filling. In bad ground, temporary timbering is placed, part of which may quently be salvaged. (For further notes on shaft raising, see Gordon shaft, Art

13. Design of Lining

Character of shaft lining depends chiefly on character of ground and of shaft. No exact rules are applicable for computation of loading and str of shaft support, and except where hydrostatic pressure is present, the stren the lining is based on previous experience under similar conditions. The must be strong enough to support the hoisting guides, and to withstand on shaft walls which usually increases with size of section. Wet ground to be heavier than dry.

In some firm rocks, it may be only necessary to keep loose pieces from dropping i shaft. In case of heavy water-bearing strata, the lining must not only resist thr walls but also dam out the water. Under these conditions, circular shafts line tubbing (Art 18) are usually best.

Materials used for shaft lining are timber, steel, C I, concrete, brick and

Shaft collar. The height above surrounding ground is determined by ties for disposing of waste rock, or other local conditions, as surface drainag a level place, collar is sometimes raised 15 to 20 ft and waste filled in arou If the shaft begins in solid rock, a collar set is framed by extending the end plates, or both, 4 to 6 ft on either side of shaft mouth; from this s hung the succeeding sets, until the first bearing set (Art 14) is placed.

Where collar set is at the surface, the extended ends of plates rest on timbers or c piers. A collar set above the ground level may be placed as described and timberi up to the required height; or the collar set itself may be raised and supported b and diagonal bracing until waste is dumped around it.

If soft overburden must be penetrated before solid rock is reached, the upp tion of shaft may be cribbed (Art 14), or preferably lined with concrete or ma

Often an open pit is made to bedrock, the sides being allowed to take their natur so as not to interfere with placing of the concrete curb. After collar is finished, th around it is filled. Guide bolts may be imbed concrete, or regular shaft sets placed inside which should extend far enough into solid rock out surface water. Both timber and concrete are frequently designed to provide foundations headframe.

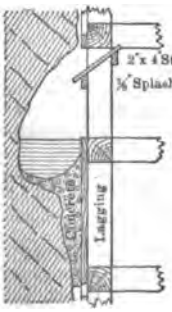

Fig 12. Water Ring for Timbered Shaft (2)

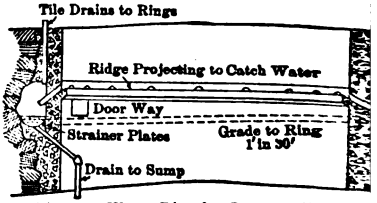

Fig 12a. Water Ring for Concrete-lined S (*Mines & Min*)

Water rings are placed at intervals in vertical shafts to intercept falling which is then led to a sump and pumped to surface. A groove is cut arou shaft to a depth of 1.5 or 2 ft, on the edge of which a dam is made of timb

...ed in clay or concrete, or of clay or concrete alone, to form a channel behind ... water is collected and led thence to a sump.

...bered shafts, water is guided into the ring by short planks placed in an inclined ... to intercept its fall (Fig 12). In concrete-lined shafts (Fig 12a), the rings are ... behind the lining, water being led to them by lines of tile pipe, placed vertically in ... the concrete; a small projection on inside of lining serves to catch the water fall... shaft. The ring should have sufficient grade to the outlet pipe.

14. Timbering

Rectangular shafts are commonly supported by timber; in recent years, the ... steel and concrete is increasing. Timber is subject to decay and in dry ... is a source of danger from fire; but, in shifting or swelling ground, it is some... preferable, due to greater elasticity and ease of replacement. Vertical shafts ...ported by **sets**, usually composed of 4 pieces of timber, framed together at ... and wedged against the walls. Types of timbering are cribbing, and ... shaft sets.

Cribbing may be of any size timber, round, hewn on two sides or squared. ...shafts are often cribbed throughout. For large shafts cribbing is chiefly ... passing through the soil ...ing bedrock. But, in ...ground on the Comstock ...ere cribbing was used ...ire depth of large shafts. ...west form is made of poles ...ired lengths and laid on ...each other; vertical strips ...side the corners keep the ...position. Planks may be ...laced on edge, with ends ...into each other, or cut ... and held in position by CLOSE CRIBBING consists ...ers placed skin to skin. ...14, 15, 16, show joints for ...bing. In Fig 16, $B = 0.5A$,

...racter of ground permits, sufficient depth is excavated to place several feet of ...at a time; a set is placed and wedged at bottom, and cribbing built up to meet ...om above. In unstable ground, the sets are placed as the excavation advances.

Shaft sets. Each set (Fig 17) consists of 2 side pieces, or WALL PLATES, ...l to the long axis of shaft; 2 end pieces or END PLATES, parallel to short ...d at least 4 posts or STUDDLES, to keep the plates in proper horiz position. ...is divided into compartments, the dividing timbers, in same plane as the ... are called DIVIDERS, centers or buntons; opposite the ends of each divider ...sionary to set extra posts. Wall and end plates and corner posts are ...of same size; dividers are generally same depth as plates, but are usu...ower, interior posts may be of same size as dividers, or smaller.

... Sec 12, Art 19) are attached to end plates and dividers. Guide posts (8) are ...ed to stiffen and support guides; they run vertically behind guides and are ...into end plates and dividers. Guide girts (8) may be provided for same purpose ...posts; they are placed horizontally, in same plane as end plates and dividers, and ...ed between midpoints of studdles. The girts take some of side thrust of shaft ...ides supporting the guides.

For proper alinement of guides, room may be allowed in design of timbering for ir of a 2 or 3-in distance piece or filler between guide and end plate or divider. In cr bering shifts under pressure, the thickness of these fillers is increased or diminis alinement, without moving main timbers.

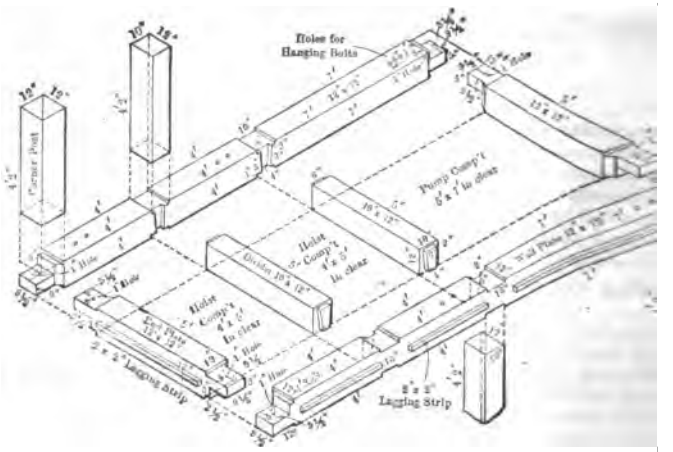

Fig 17. Shaft Set

Sawed timber is preferable to round for shaft sets, as better framed jo possible. Size of timber varies from 6 by 6 in for small shafts in good to 14 by 14 in for large shafts in heavy ground. Under ordinary condit by 10 in timbers are common. Distance between sets is variable; in so maximum is 6 to 7 ft, in bad ground they are placed closer. Usual dista to 6 ft. All the timbers of any one set are framed together accurately at wedged firmly against shaft walls by means of blocking and wedges and by at least two plumb lines hung in opposite ends of shaft.

Lagging. If ground is firm, with no tendency to shell off, no lagging i sary behind the sets. Ordinarily, however, safety demands complete c of rock walls. Lagging material: round poles placed skin to skin, or slabs and planks are common; galvanized, corrugated steel and buckl have also been used. Where several sets can be placed before being lag lagging is cut into lengths spanning 2 or more sets and shoved into Where conditions demand that lagging keep pace with shaft sets, 2 by GING STRIPS (Fig 17) are nailed to outside of wall and end plates and 2 to ging planks are set between these strips. Space between lagging and sh is packed with any available filling to prevent the walls from "starting."

To facilitate removal of broken or rotted lagging, cleats may be spiked to top an sides of the plates, to form a groove in which the ends of short lagging plank Thus placed, between instead of behind the sets, lagging is in shorter lengths and access. This method is not applicable to heavy ground.

Hanging bolts (Fig 18) are used chiefly for convenience in placing ti position. Each bolt is composed of 2 parts, exact duplicates, with hoo end to engage hook of its mate, and threaded at the other end, which through the wall plate and is secured by washer and nut.

...ance of adjustment, length of each bolt, from inside of hook to top of threaded ...d be 3 to 4 in greater than half the distance between the top of wall plate of one ...e bottom of the plate of next set. Diam of bolts ranges from 0.75 in. for small ... 1.25 or 1¾ in for large shafts with heavy timbers. C-I washers of large diam ...e used to prevent nuts from cutting into timber. 2 or 3 bolts per wall plate are ...ding on size of shaft section.

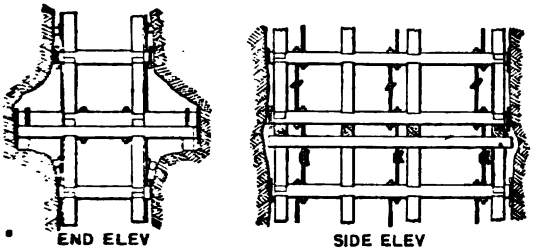

Fig 18. Bearing Timbers (8)

...aring sets, or bearers (Fig 18), are placed in the shaft at intervals of 50 ... to prevent general displacement of the timbering, and to take its weight ...cks and wedges, by which ordinary sets are secured, fail of their purpose ...or in part. Alternate wet and dry periods may cause this condition. ...ly, wedging should be such that ordinary sets are as solid as bearing sets.

...s are of two forms: (*a*) independent timbers; (*b*) extra long end plates, the ends ... are wedged in hitches in the shaft walls. Independent bearers are preferable; ... heavy timbers, of same breadth as end plates, but deeper as desired, and are ...arallel to end plates of regular set. No change is made in framing of regular plates, ...t on the bearers (Fig 18). Gains or daps in wall plate, which ordinarily receive ...uddles, now fit into a similar gain on bearer; studdles fit into gains on under side ... End plates and dividers are placed in usual manner and are sometimes bolted ...n as shown. Bearers are ordinarily placed only under end plates. Where weight ...t is great, as in large shafts, or where rock tends to slip, rendering it difficult to cut ...e hitch, they may also be placed under one or more of the dividers, as in Fig 18. ...reased strength, which theoretically should be sufficient to support the weight of ...e to next bearer above, 2 or even 3 bearers may be placed one on top of the other. ...ows sills placed parallel to wall plates in continuous hitches; on these sills the ...are securely seated and wedged.

...raming (9, 10). Usual method for vertical shaft sets is shown in Fig 17. ...ity of workmanship is important, so that each piece will go into place ...t cutting or trimming underground.

...ork is best secured by timber-framing machines, by use of carefully constructed ... or, in absence of these, by drawing a base line lengthwise on center of the most ... the 4 faces of the timber to be framed, and making horizontal and vertical ...ments with reference to this line. If the timber faces are not true, one may be ...e before laying out the framing. The face on which the base line is drawn should ...de of the shaft when set is in position.

...enons (horns) are 0.5 the thickness of the plates; those of wall plates are ... bottom half of plate; of end plates, the top half. Hence, when assem... end plates rest on wall plates.

...le is sometimes bored in center of tenons (Fig 17), and a wooden pin driven to ...ates together while erecting. A 45° bevel at each corner of a set is usually made, ...ecent plates are in contact to their full depth, thus minimizing effect of area of ...t by cutting tenons. At Butte, Mont, 0.5 to 0.25 in is generally cut off the end ...ion, to make the beveled edges draw close together while being blocked and ...levels are sometimes omitted at corners.

ment; hence it is better to set the instrument in one of the hoisting compartments a any error fall in ladderway. In steep shafts, transit must have auxiliary telesc bracket to screw into timbers, or a stretcher bar, are often better than a tripod for shaf

While it is customary to check up the setting of the timbers every few days by t tools usually employed by timbermen are spirit level, carpenter's square, plumb bo straight edge long enough to span 3 sets. The straigh[illegible]e is often made as one si framed triangle, the top of which is horiz when the b[illegible]h of the straight edge is inclination of shaft.

Horizontal alinement may be secured by making use of tacks placed as described transit alinement. In setting a sill, a string is stretched from a tack in the new tim one similarly located several sets above. The plate being placed is then wedged until the string is exactly over the tack in last completed set. Sill is leveled with level. The hanging-wall plate or cap is set by stretching string as for sill, and at th completed set drop a plumb lin[illegible] from the string and wedge the cap over until plum hits the footwall string.

Cylindrical shafts may be lined during sinking by lagging driven behind wood steel rings placed at vertical intervals of 4 to 6 ft (14), which in turn are kept in pla wood or steel distance pieces. Steel plates are also used. These forms of lining ser temporary support previous to placing permanent metal or masonry lining.

Swelling ground is difficult to hold unless provision is made for cutting away protr rock and easing the shaft timbering. This is best done, without interruption of hoi by making the shaft opening large enough to allow a 2.5 to 3-ft space outside of re shaft sets. Auxiliary or jacket sets (8) are then placed and wedged around regular Floors may be laid on jacket sets and lagging placed outside of them in the regular in some cases regular are also boxed in with p In space thus prov work of easing timbers proceed as required.

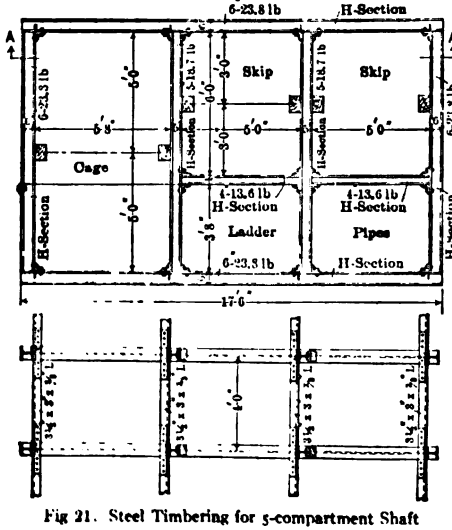

Fig 21. Steel Timbering for 5-compartment Shaft

15. Steel Linin

Steel shaft "timl ing" is often used ins of wood for both ver and inclined shafts All members used to f timber sets find t counterpart in steel bering.

Stresses in **wall** and plates are: **bending**, d side pressure of rock and compression, due t reactions of adjacent pl Stresses in **buntons** or d ers are: direct compre in case of vertical sh while in inclines or type of shaft in mo ground, the buntons also resist **bending.** or **studdles** are in d compression in vertical shafts but are subject to bending in inclined shafts. **Hence** plates and dividers, rolled shapes must be selected which have a comparatively large radius of gyration, and are equally strong about both axes of symmetry (Sec 43).

The H section is used extensively; it is adapted to withstand combined stresses, affords ample bearing against the sides of shaft. This shape has also been used for guides, cast-steel racks, sometimes bolted on the steel guides to engage the safety seem of doubtful value due to the heavy stresses and shocks. **Angles** are largely us

...and do away with necessity for permanent hanging bolts. I-beams are commonly ...or bearers. T-rails alone or reinforced with angles, and steel cross ties, have been ...wall and end plates; I-beams, double channels, and Z-bars for buntons; and rails ...where the weight of shaft is carried by lower bearers. Where there is enough ...below the lowest set to permit turning into position, each set may be riveted to... surface and lowered intact, chain blocks being used to swing it into place. If ...ary to carry timbering so close to bottom that there is insufficient room to turn the ...et, or where it is difficult to lower the entire set without interfering with dividers, ...be shop-riveted in parts and the underground assembling done with bolts.

16. Concrete Lining

Reinforced-concrete shaft sets, with members corresponding to those of ...sets, have been successfully used in both vertical and inclined shafts (11). ...vidual members are cast in steel or wooden forms.

...Iron Mining Co, Mich, used a 1 : 2 : 3 mixture, poured wet, in molding sets for ...shafts; Ahmeek Mining Co, Mich, used 1 : 3 : 5 mixture for plates and dividers, ...: 4 mixture for studdles of an 80° inclined shaft. After removal of forms, mem... allowed to harden for several weeks before placing. Reinforced concrete slabs, ...2 : 3 or 1 : 2 : 4 mixture, are molded for use as shaft lining between successive sets ...partitions between compartments. Where used as lagging between sets, the slabs

...a set has been blocked into alinement it is sometimes tied to the rock by placing a ...ottom and filling around set with concrete. In some cases, members are molded ...forcing extending from the ends, which serves to bind the sets to a mono...

concrete lining poured after they are in place. Wall plates of long shafts, on acco their great weight, are sometimes made in 2 or more sections. Holes are cored to assembling and hanging bolts.

In a 3-compartment shaft of the Ahmeek mine (43), concrete sets (Fig 22) repla by 12-in timbers. Costs per set delivered at shaft mouth: timber, $37.60; co $22.50. Unit costs: timber, $28 per M; crushed stone, 35¢ per cu yd; sand, 60¢ per cement, $1.15 per bbl; reinforcement, $12 per shaft set. Labor of placing a concr is more than for timber because of its weight. 7 men placed one set per 9-hr shift.

Monolithic concrete lining (2, 11), both with and without reinforcin been successfully applied to inclined and vertical shafts of all shapes, thou flat inclines some reinforcing is needed.

Concrete lining may be designed to resist hydrostatic pressure and dam c water. Except in passing through a zone of surface water, however, it is ally best to collect water in rings (Art 12) if in moderate volume, and pu surface; excessive volumes are handled by grouting (Sec 8, Art 7).

Concrete lining is sometimes poured around steel or molded-concrete shaft s other cases, dividers of wood, steel or reinforced concrete are placed while pouring. neither sets nor dividers are employed, one or more reinforced curtain walls betwee partments may serve to stiffen the lining; these walls having openings at inter prevent injury from suction when hoisting. Bolts for guides are imbedded in th walls, or holes are cored in dividers and end plates to receive them. Concreting started at the bottom of a shaft; if so, temporary timbering is usually required for

Details of monolithic lining. After sinking as far as is safe, hitches ar bearing timbers placed, and a platform placed upon them. With the pla as a foundation, forms are placed, a temporary floor laid on top of forms, an concrete poured.

Mixtures from 1 : 2 : 4 to 1 : 3 : 6 have been successfully used, depending on m available and strength required. Concrete is mixed on surface and lowered in bu or delivered through a pipe, say 4 in diam. Buckets with distributing chutes at b place concrete directly in forms without shoveling; where delivered by pipe, it r received in similar buckets and placed as desired.

If the rock section has been broken to nearly correct size, inside forms alone are re If large cavities exist in rock walls, outside forms with back filling are necessary; o ties may be filled with dry rubble, which answers both as outside form and fillin such places it is customary to increase the thickness of w use steel reinforcing, or both. It is important that all inf water be cut off by the grouting, or piped through the forms concrete is placed, to avoid separation of cement from the Minimum thickness of concrete is from 8 to 18 in, dependi character of ground.

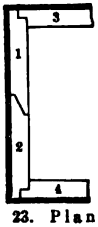

Fig 23. Plan of Wooden Form for Concrete Lining

Forms are of wood or steel, built in sections from 2.5 to high; aver about 5 ft. They should be designed to strip after concrete is set. If greased before pouring concrete, come away easier, and leave better surface. WOODEN FORM usually of 2-in plank dressed to uniform size, and tied togeth wood or steel bracing. Fig 23 shows a simple type (the nu indicate order of stripping). STEEL FORMS, of ⅛ to ¼-in p with angle bracing, are extensively used for circular and elli shafts (12.)

Reinforcing for concrete linings is commonly of old mine rails or hoisting rope; s ard steel shapes, or steel bars and expanded metal, are also used.

Concrete blocks have been used in Europe for shaft lining. An interlo reinforced block molded in Z-form has been successful in Belgium. After pl the blocks, spaces behind them are filled with concrete.

Steel and wood shaft timbering and lagging, covered with wire netting, have been c with a layer of concrete grout 1.5 to 2 in thick, applied by a cement gun under 25 to pressure. The grout serves to fireproof and lessen decay of wood and prevents cor of steel.

17. Masonry Lining

Materials. In Europe cylindrical shafts are common and masonry WALLING is usually used as lining, where the volume of water is not excessive. Good hard-burned brick, or durable stone or cement blocks laid with hydraulic cement, are the materials used. For small-diam shafts, brick should be shaped to curvature of shaft; for diam over 12 to 14 ft, ordinary straight brick are used. Cut stone is too expensive where other material is available. Where water under low head is to be dammed back, a special form of brick lining (COFFERING) is used (see below); for heavy pressures, C-I tubbing (Art 18).

Details. Shaft is sunk until strata is reached firm enough to permit placing foundation for lining. These foundations or WALLING CRIBS are usually spaced 30 to 50 ft apart. In very soft ground, a temporary lining (Art 14) is used. Diam of shaft is enlarged 2 to 3 ft to form seat for crib, this work being done with as little blasting and shattering of rock as possible. In firm ground, walling may be started directly on the rock seat. Usually the cribs are of wood or C-I, made in sections, and wedged or grouted into position. In very soft ground, the crib is laid on 1 or 2-in iron bars, driven into holes 2 to 3 ft deep around the circumference of shaft. Thickness of walling is usually 9 to 18 in. Space between lining and rock is filled with gravel, cinder, or concrete. Various types of curbs have been devised for placing brickwork, so that walling and sinking may proceed simultaneously (6).

Fig 24. Walling Crib and Water Ring Combined

Water rings. In wet strata weeping courses are left in lining, and water collected in wood or C-I water rings or troughs, which are often combined in one casting with walling crib (Fig 24). Above each water ring, the walling for a height of 4 or 5 ft is tapered back, so that 3 to 6 in of clear space is allowed for ring (Fig 25). Under the walling crib, a supporting shoulder of rock, 3 to 5 ft deep, is left before enlarging to full rock section. Great care should be taken in removing this shoulder when completing the next lower walling section.

Fig 25 Walling and Water Ring in Place

Coffering (1) is watertight lining formed by several concentric brick or concrete-block walls, with a space between filled with concrete, steel plates set in concrete, or clay. It must start from an impervious stratum and rest upon a watertight foundation or wedging crib, as used for tubbing (Art 18). There are usually 4 to 8 concentric rows of brick, often laid in stretcher courses. The bottom course of alternate rows frequently consists of split bricks, so as to break joints vertically. Hydraulic cement is used. Formulas have been derived for thickness of coffering (14).

Cost. English engineers place cost of WALLING CRIB at $25 to $50, and cost per ft of ordinary brick WALLING at $0.75 to $1.00 per ft of shaft diam; bricks at approx $5 per M. COFFERING costs more, depending upon its thickness and cost of enlarging shaft to admit extra thickness of brickwork. Costs in England for 20-ft shaft were $33 per ft; for a 16-ft shaft, $17 per ft.

18. Tubbing

Conditions for use are: a heavily water-bearing rock formation, underlaid by impervious stratum, which in turn lies above the mineral deposit. The quantity of water must not be too great to be pumped during sinking.

Construction. Tubbing is a watertight lining, usually of C-I rings, made in segments. The lowermost ring rests on a WEDGING CRIB, which makes a tight joint with the impervious stratum. Most of the ground-water is permanently shut out, thus greatly reducing the pumping cost during the life of the mine.

The wedging crib (Fig 26), of wood blocks, or better of C I, is made in segm and wedged tightly against the shaft walls (see Art 17).

The wedging crib seat is prepared by carefully dressing the rock around the shaft p eter. A gasket of thin pine boards, sometimes covered with tarred flannel, is laid b the crib is placed, or the crib may be set on a bed of fre poured concrete. After crib is in position, pine wedges driven filling space between it and the rock walls. Oak and sometimes follow the pine wedges, the steel being withdr and hardwood wedges driven into the cavities. The crib t to spring under the tension of wedging, and is propped d from the walls. Dry moss is sometimes placed in space bet crib and rock, and wedges driven into the moss. Two or cribs may be laid, one on top of the other. Instead of wedg the crib is sometimes secured and the joint made watertigh tamping concrete behind it and the 2 or 3 rings of tub next above.

Fig 26. Wedging Crib and Outside-flange Tubbing

There are 2 forms of C-I tubbing: (*a*) outside flange, (*b*) side flange. Tubbing with outside flanges and ribs is cas segments 1.5 to 3 ft deep, 8 to 12 segments to the ring. A in center of each segment facilitates handling and serve relieve water pressure during erection; the hole is subseque plugged. Gaskets of dry pine or sheet lead are placed between the segments, the jo of which are tightly wedged, after being placed in position. Tubbing with inside fla and ribs is cast in segments 2.5 to 5 ft deep. Flanges are carefully machined and bo together with lead gaskets. No wedging is necessary. The space between the tubl and shaft walls is filled with concrete.

Advantages of inside flanges are: (*a*) tensile strength is greater, as inside ribs ar compression; hence less weight is required, and deeper rings are possible, at less cost ft; (*b*) the wedging required with outside flanges throws strain on the inner edges of plate, whereas it is evenly distributed with bolted, inside flanges. Disadvantage of side flanges and bolting is that the rings are rigid, and shifting ground causes abnor strains in the lining.

System of suspended tubbing, used in Germany, requires no temporary timbering cuts off part of inflowing water during sinking (15).

Strength of watertight lining depends on the lining material, diam of shaft, and h of ground-water, which is usually taken as the entire height of tubbing above the *point* question. Stresses due to rock pressure and wedging are indeterminate; corrosion by a water is also an important factor. It is customary to use several graded thicknesses of t bing, from maximum at the bottom to a minimum at the top, based on hydrostatic press

A number of formulas have been proposed for thickness of tubbing. Lupton (17) gi for outside-flange tubbing for a depth of 200 ft: $x = \frac{D}{20} + \frac{1}{8}$ in, in which x = thickn in; D = diam, ft. This formula is used in connection with the following, good for any dep $y = x\sqrt{\frac{P}{200}}$, where y = thickness, in, for any depth other than 200 ft; x = thickness 200 ft, as found by first formula; P = depth, ft. Thickness should never be less than 0.5

For width of flanges Lupton gives the formula: $z = A\sqrt[3]{\frac{D}{200}}$, where z = width of flan in, for any depth other than 200 ft; A = width of flange, in, for 200 ft depth as given bel

Diam of shaft, ft	Width of flange, in	Diam of shaft, ft	Width of flange, i
Under 10	4.0	16 to 18	5.5
10 to 12	4.5	19 to 22	6.0
13 to 15	5.0	.....	.....

Thickness of flanges is same as that of the plates.

A German shaft, 16.6 ft diam, tubbed from 394 to 581 ft with flanges inside, was divid into 2 sections. Thickness of metal: bottom section, wedging crib 2.36 in, tubbing 2.16 i top section, wedging crib 2.16 in, tubbing 1.97 in.

Examples of English Shafts Lined with Outside-flange Tubbing (14)

Depth of section tubbed, ft	Thickness of tubbing, in	Diam of shaft, ft	Depth of section tubbed, ft	Thickness of tubbing, in
101 to 303	7/8 to 1 7/8	16	340 to 450	2
110 to 255	1 1/2	11	60 to 260	3/4 to 1 3/4
275 to 340	1 3/4	10	300 to 420	1 1/2 to 1 7/8

983. In England (6, 16), cost of tubbing installed ranges from $40 to $100 ... shaft; castings cost $25 to $35 per ton, and placing $6 to $10 per ton. ... it for a 14-ft shaft, were: 0.75-in tubbing, $44; placing, $5; gaskets, ... etc, $2. Preparing seat and placing wedging crib, $200.

18. Kind-Chaudron Process (15, 44)

Conditions for use: heavily water-bearing rock formation, with an impervious stratum overlying the horizon to be reached, similar to the conditions ... lining by tubbing (Art 18), but where the inflow of water is too great ... ped while sinking. The stratigraphy essential to the success of the ... is rare in the U S, but common in parts of Europe, where about 90 Kind- ... shafts have been sunk.

Method. The shaft is excavated by a boring process, under water, by means ... drop tools, called TREPANS, the method being an extension of the rod ... toring (Sec 9, Art 5, Canadian rig). The water stands at its natural ... l the work is finished. A small shaft may be bored first and then enlarged to full diam, or the full section bored in one operation. On completing ... seat is prepared to receive the bottom section of lining (tubbing), called ... SHOE, which automatically makes a tight joint with the underlying ... stratum. The tubbing is put together at the shaft mouth, ring after ... added as the entire lining is lowered through the water. When the ... in place, the space between it and the shaft ... with concrete, and the shaft is pumped ... The success of the process depends upon the ... tightness of joint between the tubbing and ... its stratum.

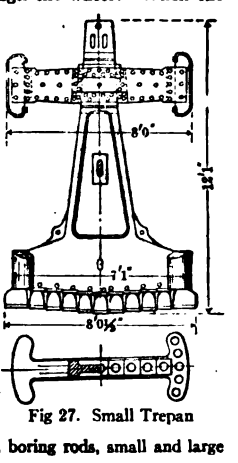

Fig 27. Small Trepan

... (15) says that sinking by ordinary methods is ... the Kind-Chaudron process for mean depths ... 100 ft, with less than 1 700 gal of water per ... mean depths less than 300 ft with less than 900 ... For depths greater than 500 ft, where water-... are at least 160 ft thick, and make more ... gal per min, the Kind-Chaudron process is ... the cheaper.

... here it is anticipated that this process will ... the shaft is commonly started by ordinary ... are being taken to keep the walls of com... clear of all projections which might ... by interfere with the passage of boring ... shaft were suddenly flooded.

... ed consists of a suitable headframe (with ... handling the heavy boring tools), power plant, boring rods, small and large ... bits and special tools.

... A shallow hole, the diam of small trepan (Fig 27), is made in the center of ... assist in starting the trepan, which cuts an advance center bore 4 to 10 ft diam. ... usually kept at a minimum distance of about 30 ft in advance of the enlarge-

ment, but it is sometimes drilled to the entire depth before enlarging begins. C from small trepan are removed by sludger (Sec 9), while those from large trepan are and periodically raised, in a large bucket suspended in the advance bore. Drillir are attached to rods suspended at surface from the walking beam by a temper scr 9, Art 5), which feeds down as shaft is deepened.

Trepans are massive steel frames, to the lower edge of which are at chilled-steel bits weighing about 100 lb each. Bits are placed unsymmet to cover entire area of shaft bot trepan rotates; they are also set t the shaft bottom towards cente facilitating removal of cuttings. T are inspected frequently and du removed.

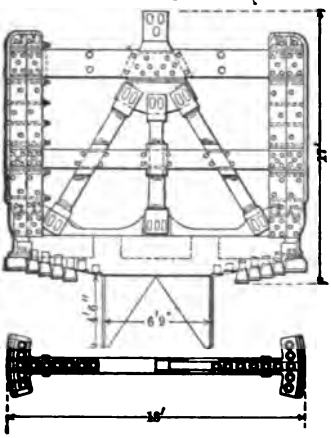

Fig 28. Large Trepan

Weight of Trepan: for small diar 2 to 15 tons; for large, 15 to 30 to enlarging trepan (Fig 28) has a project tion extending into advance bore, t keeping proper alinement. This pu also served by attaching to trepan head fitting in the shaft. These cro may carry bits to dress down the sha Strokes per minute vary from 8 to 25 of stroke, 6 in to 2 ft.

Temporary lining. If shaft wal badly, caving areas may be lined tem with sheet-steel casing, supported shoulder of rock left for the purpose pended from surface. Diam of sha be reduced below such temporary lini

Permanent lining. When sh been sunk well into the impervious stratum, the bottom is cleaned by a tool, and moss-box and tubbing lowered into place. The lining has inside (Art 18), and all flange faces are machined and packed with sheet-lead gaskets before being bolted together at surface.

The moss-box (Fig 29) is formed by constructing the 2 bottom tubbing rings so that they can telescope; the annular space between bottom ring and shaft wall is filled with moss secured to bottom ring by wire netting while lowering. When bottom ring reaches its seat, the weight of tubbing above forces second ring to telescope over the first, compressing the moss against shaft walls and forming a watertight joint.

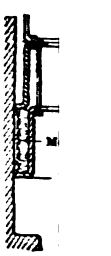

Fig 29. Se Moss-b

In deep shafts, the tubbing becomes excessively heavy; it may be rendered buoyant by inserting a false bottom or diaphragm, above the moss-box. In this diaphragm is placed a vertical EQUILIBRIUM PIPE, controlled by valves which admit ballast water as necessary. Section after section of tubbing is added, and the whole lowered until the buoyancy is greater than the wt of tubbing. Enough water is then admitted to sink the lining and compress the moss. Cement grouting i lowered in trip-bottom boxes, to fill the annular space between shaft walls and t When the concrete has set, the shaft is pumped out and the false bottom r Wedging cribs are placed below the moss-box and sinking is resumed by ordinary m

Modifications. The moss-box has sometimes been omitted, the concreting h pended on to make a tight joint. In this case, special bits are placed on the enlarg pan to cut a level seat for the bottom flange of the lining. A modification introd Lippman is to bore out the entire shaft in one operation, using a trepan of specia

Speed and cost. Aver speed of sinking in northern France is given (6 to 33 ft per month, to depths of 600 ft; diam, 8 to 12 ft; cost, $66 to $200

... sinking 14.5-ft diam shafts in the Ruhr district, Germany, to mean depths be... and 1 148 ft are given as follows (18):

Negaunee No 3 shaft, Negaunee, Mich (38), 17 ft diam, was begun by an 8.5 by [illegible] from the 806-ft level to top of rock, 68 ft below surface. Raise was then [illegible] to full section, concreted, and steel dividers placed. Following costs per ft are [illegible] ft of rock section; raising, $18.68; enlarging, $17.33; steel dividers, $10.06; [illegible] concrete forms, $1.26; temporary plant, $6.74; concrete, $17.22; compressed air, [illegible] per ft, $72.17. Aver thickness of concrete, 16.2 in.

Gordon shaft (45), Ducktown Sulphur, Copper and Iron Co, Tenn, was excavated [illegible] of 1 175 ft in comparatively dry, very hard, silicified mica schist, by a com- [illegible] of sinking, raising and reaming. Size of shaft, 7. by 14 ft. Shifts per day, 2 [illegible].

[illegible] ft of shaft was made up as follows: collar 8 ft above surface; 63 ft reamed [illegible] old shaft and 99 ft sunk. Upper 84 ft were timbered and lagged; shaft sets, 12 [illegible] dividers, 8 by 10 in; sets, 5-ft centers. Rest of shaft was in solid ground and [illegible] omitted; dividers and end plates necessary to carry guides were set in hitches. [illegible] 170 to 629 ft, drifts were run from 5 levels to line of shaft and a raise, about 5 ft [illegible] was started at 5 points, sinking being carried on simultaneously from surface. The [illegible] were subsequently enlarged to full section. Shaft was put in operation to a depth [illegible] (including 15-ft sump) in 13 months; approx monthly aver, 49 ft. Drills per [illegible], 2 hammer stopers; reaming, 4 3-in reciprocating. Number of men per [illegible], 2 drillers, 1 nipper, trammers as needed; reaming, 8 drillers.

[illegible] to 860 ft, the shaft was sunk, as there were no workings beneath to permit [illegible]. Although every facility then available was employed, the sinking and equipping [illegible] section proceeded at an aver monthly rate of less than 17 ft. Drills per crew, 4 [illegible] reciprocating. Number of men per crew, 1 boss, 8 drillers, 1 hoistman, 1 lander.

[illegible] 860 to 1 175 ft, the shaft was sunk with 6 jackhamer drills, and with increased [illegible] and hoisting facilities. A maximum of 80 ft was sunk in a month of 47 9.5-hr [illegible] the aver speed being 63.5 ft per month. The 300 ft of divider timbering and hitch [illegible] (5 ft of the 50-ft sump being untimbered) was done in 1 month.

[illegible] costs apply to first 860 ft.

NOTE. — Numbers in parentheses in text refer to Bibliography at end of the section.

1. Difficulties in Sinking in Soft Ground

Underground water is the prime cause of the special difficulties met in sinking through workable soils, consisting of sand, gravel, mud, or a partially cemented mixture of these. Some pumping capacity is usually required at once, for it is impossible to check inflow by sealing fissures with cement grout, as can be done in water-bearing rock. The water must either be pumped continuously, or excluded permanently by a lining strong enough to resist external pressure corresponding to head of water or of semi-fluid material. The cost of such lining, expense of pumping during construction, and general engineering difficulties involved in sinking under these adverse conditions, have led to the invention of methods for excavating and sinking the lining WITHOUT PUMPING. The ground water is allowed to stand at its natural level, and all excavation is done under water. Finally, the lining is sealed to underlying rock, or other impervious stratum; after which the water is pumped out, and sinking is continued by ordinary means.

Running ground is a term applied to unstable materials, ranging clean dry sand to semi-fluid silt. Presence of water increases instability, is a more serious obstacle to sinking than the water itself. In fine, sand, a relatively small quantity of water acts as a lubricant, converti material into a slow-moving fluid which will penetrate the smallest leaks lining, will flow under and around lower edge of lining and rise in the but can not be pumped. Continued removal of such material from shaft slips and falls in the ground outside the shaft, and produces irregular a cessive stresses in the lining, often distorting it and causing surface subs around shaft mouth. In some cases this subsidence has affected an a more of surface, wrecking neighboring buildings and foundations. Her preparing to sink through unstable ground, the possible result of subs must be considered in laying out the plant and its foundations. Boilers pressors, and engines should be set well away from shaft mouth; derrick have a boom at least 60 ft long and should be erected on a spread foun which can readily be jacked up. If a headframe be used it should be mo on long trusses spanning the shaft; independently supported derricks a ferred to headframes for soft-ground work.

Boulders in soft ground cause much trouble, and their probable presence or a often determines method of sinking to be adopted. When sinking in running gr is always necessary to force down the lining somewhat in advance of excavat minimize flow of material into shaft; this may be difficult or impossible, if a bou imbedded in the ground directly under edge of lining. As an attempt to dig do remove the boulder is liable to result in a violent inrush, it is usually necessary t the boulder in place.

External pressure, which affects the design of shaft lining, depends on: depth cavation, nature of ground, and quantity of water. Where seepage is to be allo drain into the shaft, the lining at any given depth must be strong enough to re corresponding hydrostatic pressure. In heavy, running ground this pressure may exceed hydrostatic pressure, since it is due to a depth of fluid composed of water an or mud, of greater specific gravity than that of water alone. The lining must als stand severe localized stresses caused by irregularities in sinking.

Methods of sinking in soft, water-bearing soils: (*a*) Linings construc the shaft as excavation progresses, including various types of timbering, poling and spiling, and the shield method. (*b*) Linings constructed at s and sunk as excavation advances, including open and pneumatic caisso "drop shafts," sunk by their own weight or forced down. (*c*) Solidificat the material in advance of sinking, including the freezing process for sand, and the cement grouting process for wet, seamy rock.

2. Timbering and Piling Methods

Characteristics. To resist normal earth pressures to depth of, say, requires merely the setting of sufficiently heavy timbers close enough tog but in unstable ground, to build a timber lining strong enough to resist dencies to distortion, due to shifting and falls of soft material behind the li is practically impossible. The solution of the problem is to prevent in that cause falls, by driving a continuous row of sheet piles or poling b around area to be excavated, in advance of excavation, or by forcing do shield. The tendency of the surrounding material to flow under lower ed lining into the shaft is thus checked by the weight of material inside.

Limiting conditions under which timbering is applicable in soft ground are: (*a*) of shaft at which external pressure is not greater than a practicable timber *linin* safely carry; (*b*) soil which permits piling to be driven far enough ahead to prevent in at bottom, but, at the given depth, will not exert enough fluid pressure seriously to d

...ing by bending lower ends inward. The behavior of different soils is described in ... given later. To a depth of about 80 ft, timber lining is cheapest; but, since ... lacks durability, a permanent shaft in soft ground must be excavated of large ... section to include a masonry lin... adding added cost.

In ground ...ing few boulders, 4 by 10-in tongued and grooved piles can be driven or jetted in ...ths, making a net depth, including necessary lap, of about 12 ft per course

Fig 7. Detail of Joint of Inner Course of Sheet Piling under Cross Struts of Fig 1

Splined 6 by 10-in piles can be driven in 26-ft lengths by using a pile driver (pref steam hammer), making net depth of about 20 ft per course; but at this depth tion of lower ends and consequent leaks in lining are probable. When, after sinkir larly, a pile suddenly stops, presence of a boulder is indicated; the adjacent pil then be driven home, and boulder dug out or broken up at once. If ground run and yet contains many boulders, no type of sheet piling will give good results.

Interlocking steel piling. Among well-known designs are those of linger, U S Steel Corp (Carnegie) (Fig 5), Lackawanna Steel Co (Fig 6 Friestedt. Some are of channels and angles, others of special shapes. I as to cross-sections, sizes, and weights can be obtained from makers' catal Interlocking 12-in steel piles can be in lengths of 40 to 50 ft without sepa and a depth of 75 ft has been reache courses (see Example III, below).

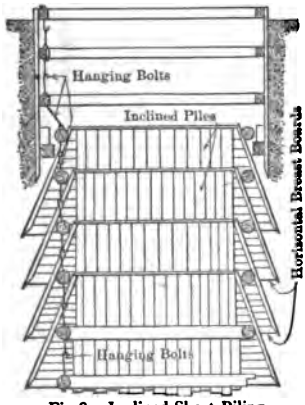

Fig 8. Inclined Sheet Piling

Inclined piles or poling boards (are sometimes used in deeper sha avoid sacrificing area. This is a mo tion of forepoling, common in tunneli ground (Sec 6, Art 19), but is not adapted to shafts. Having carried the shaft with vertical sheeting unt ground is reached, a set of timbers s than those above is so placed on the b that a uniform space, slightly wide thickness of proposed poling boards, between the backs of these timbe the vertical sheeting. The points of boards are then entered into this spac the boards driven on an outward slant. Length of boards must be mor double the out-to-out spacing of timber sets; when driven home they bear a outer edge of bottom set of timbers and inner edge of set above. The completed course thus forms a flaring wall, within which another set of timbers can be placed without reduction in shaft section. Especial care is taken in excavating at corners and opposite cross braces, where gaps are necessarily left to be closed by short horizontal BREAST BOARDS. The timber sets are tied together with hanging bolts, and the whole structure may well be suspended from a surface truss or heavy collar set. A modification is shown in Fig 9. Inclined piling is adapted to hand work, but is not suitable for very soft ground nor great depths, owing to difficulties of keeping tight a lining with so many joints, and the multiplied stresses in timbers, due to lever action of poling boards.

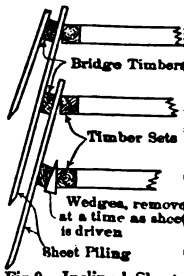

Fig 9. Inclined Sheet Modified

Shields. In very soft ground, iron shields with doors, that can be opened to excavation or closed to stop an inflow of material, are sometimes used (Fig 10). are forced down with jacks bearing against the lining, and are provided with a v tail plate inside which the lining is built up, usually of heavy horizontal plank la wise. The lining is tied together by spiking on vertical planks, and to prevent ment it is usually suspended from heavy beams or trusses across collar of shaft; shoe of the shield must also be suspended, so that, if one end hangs on a boulde other is in soft material, it will not be distorted or fall away from lining. Depth is l usually to about 80 ft, since below that the upward pressure of running ground

...ack a shield against. Fig 10 shows method of hanging shield from a suspension ... is advantageous also with other types of timber lining in bad ground.

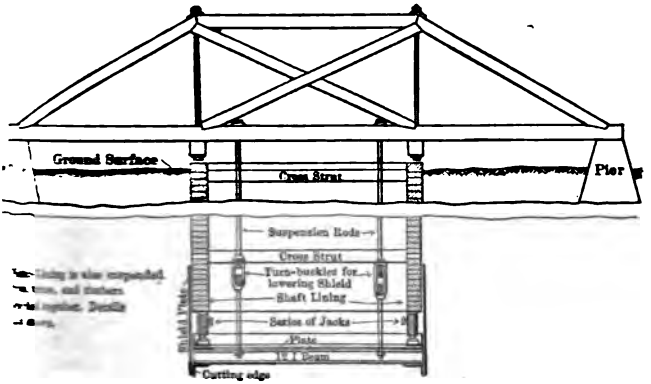

Fig 10. Shield Suspended from Truss

Excavation. Boom derrick, equipped with double-drum engine, has super- ...headframe for sinking in soft ground, either by timbering or by open or ...caisson methods, because of its lightness and flexibility. The boom ...raised or lowered to cover entire area of shaft, a useful feature in placing ... Boom should be at least 60 ft long, and derrick set well back from ...and so constructed that it can be readily raised if ground settles. Ma- ...usually dug and loaded by hand into shaft buckets (Examples I and ...); but in large shafts, where piling is driven well ahead, and in open ... an orange-peel or clam-shell bucket may be economically used (Ex- III). These require a third drum on the engine. While removing ... from beneath points of sheet piles, or cutting edge of shield or cais- ...must be taken to prevent an inrush of soft ground. It is often neces- drive short sheet piles around a boulder projecting into shaft, until its ...be reached, and then to break it with light charges of dynamite. In ..., suction pipe should be kept well below general level of excavation, ...t be necessary to drive a small sheeted sump in advance. In several ...quicksand has been successfully drained by driving into it perforated ... to which the pump suction was attached. On completing a stretch of ...t is essential to its stability that all water coming through it shall be ...clear, carrying no sand or mud. This is best attained by liberal use ...rammed behind the lining and into every crack and crevice. Sealing a ...lining to rock is not difficult, as the piles, if driven home, fit them- ...irregularities of rock surface. Subsequent excavation of the first 10 ... of rock must be done with extreme care; the first cut should be line- ...channeled entirely around the shaft.

Examples

Shaft 5, Wallkill siphon, Catskill aqueduct, was sunk through 40 ft of wet silt ...sand with 3 successive courses of 3 by 12-in by 16-ft tongued and grooved yel- ...plank. Top course, 19 by 30 ft outside; second, 16 by 27 ft; third, 13 by 24 ...shaft, 9 by 20 ft, inside timbers. Material excavated by hand and raised ...ck. A serious run of soft ground occurred under first course of sheeting, which ...aft out of line and made subsequent steps slower, more difficult, and expensiv

Average progress, 9 in per day. Cost per ft: timber (1200 ft b m), $30; labo supplies and miscellaneous, $24; total, $200. (Compare Example I, Art 3.)

II. Shaft 5, City tunnel, Catskill aqueduct, was sunk through 30 ft of fir bearing sand, close to brick conduit of old Croton aqueduct, and great care was t to prevent undermining the latter. Finished shaft is 14 ft diam, with reinfor crete lining, 2 ft 6 in thick, through soft ground. One course of 4 by 12-in tongued and grooved sheet piling was driven; supported by 5 sets of 12 by 1 bers, 35 by 35 ft over all, braced diagonally across corners to leave unobstructe onal opening. These outside dimensions were adopted on account of the shaft c A second course of 12-in U S Steel Corp sheet piling (Fig 5) 16 ft long, was d rock; supported by 6 octagonal sets of 10 by 10-in timbers, 20 ft 8 in across and for added stability. Material excavated by hand and raised with derrick; pilin with steam hammer. Some trouble was experienced by the separation of lowe steel piling, due to boulders, and an oxy-acetylene torch was used to cut off sev which projected into shaft. Progress, 9 in per day. Cost of first lift per ft: tim piles, $37.50; labor, $97.50; supplies and miscellaneous, $20; total, $155. second lift: timber, $8; piles, $35 ($15 allowed for salvage); labor, $115; supp miscellaneous, $25; total, $183 per ft.

III. Shaft for pier foundation, Tunkhannock viaduct, (21) was sunk through 75 ft of earth and sand by 2 courses of Lackawanna Steel Co sheet piling The 30-ft pilings for first course were assembled around a rectangular timber fra driven successively 2 or 3 ft at a time, until they reached their full depth, materi excavated meanwhile with derrick and grab bucket. Sets of 12 by 12-in timl placed as excavation advanced. A course of 45-ft piling was then assembled a frame concentric with first course, and 4 ft 8 in outside of it, and driven grad about 15 ft. The earth between it and the inner course of sheeting was ex outer course being braced against outside of inner course and by timber sets ab of inner course. Driving the inner course was then resumed, the sets of interior being shifted downward as excavation advanced, new sets of bracing for outer cou added above top of inner course. Thus the inner course was driven to rock a course to its full depth, without interference between the two sets of bracing.

3. Open Caissons (Drop-shafts)

Characteristics. Strong heavy caisson, of inside dimensions equal greater than those of proposed shaft, is constructed on surface, and s excavating within. This caisson or lining may be circular, rectangular, other desired shape. The first section is built on a shoe or cutting ed when sunk to nearly its full depth another section is started on top an ing is resumed; the process is continued until cutting edge reaches rock VANTAGES: (*a*) lining is built above ground, where construction is cheap easiest; (*b*) since weight is desirable in sinking, a permanent masonry can be built at once, of sufficient strength to resist any probable stress; cavation is done in a comparatively open space, unhindered by cross likely to be struck or knocked out by a bucket, and consequently wi risk to workmen; (*d*) completed lining is waterproof; (*e*) weight and s of lining are sufficient to crush or push aside boulders that would stop an of sheet piling. DISADVANTAGES: (*a*) under certain conditions it is diffi keep caisson vertical; (*b*) skin friction increases rapidly, and at consi depths lining must be heavy and expensive, to overcome friction; (*c*) in r ground, large excess of material is always removed through caisson, panied by settlement of surrounding surface and damage to adjacent stru For a temporary shaft, the cost of materials for a lining heavy enough t and strong enough to resist strains of sinking, is much greater than co timber sheet-pile lining which will serve the purpose if it can be plac cessfully. On other hand, in a permanent shaft the masonry caisson p the permanent lining, and cost of temporary timber is eliminated.

Materials. Open caisson was probably first used for sinking water wells, the caissons ... stone or brick masonry, as timber is usually too light to sink. The masonry ... upon a timber curb or SHOE, with steel cutting edge. Applying the idea to mine ... masonry stone masonry proved to be too weak to stand the uncertain stresses ... Hard-burned brick, well laid in cement mortar, is better, but still too weak ... caissons. The next step was a compound caisson, an outer sheet-steel shell, ... riveted to cutting edge, and lined with brick. Compressive stresses are borne ... and tensile by the steel, and caissons so constructed have been sunk to great ... difficult material. The widely different elastic properties of a thin steel shell and ... brick lining prevent the compound structure from acting as a unit, and serious ... in the brick are possible without rupturing the steel. Also, with compound, as ... stone or brick caissons, the only possible shape is circular. Development of ... concrete has produced a material so well fitted for caisson construction that ... used almost exclusively for important work. Concrete is as heavy as brick or ... a tougher and cheaper. With thorough reinforcement, and bonding between ... courses, a concrete caisson acts as a monolith; since its walls will bear both ten... compressive stresses, it may be rectangular, oval, or circular in section.

Design and construction. Factors to be considered are: (*a*) probable skin ... at different depths, and weight necessary to overcome it; (*b*) stresses ... sinking; (*c*) permanent exterior earth pressure. The last is least im... for any caisson heavy and strong enough to sink safely will stand the ... There are no exact rules for calculating stresses. Examples are ... of successful caisson work, with statement of skin friction exist... different depths. FRICTION of circular caissons is generally less than that ... angular, under similar conditions, because of the arch action of sur... soil. Friction is reduced by making outer surface true and smooth; ... well braced concrete forms are essential and for important work these ... be built or faced with steel plate. The outer surface is often given ... inward batter, so that as the caisson sinks it will tend to pull away from ... ing soil; though this action takes place in fairly firm material, in run... it is doubtful if anything is gained. Another device for reducing ... is to build occasional horizontal pipes into and extending through ... walls, through which water or air under pressure can be pumped ... ground to loosen its hold. Friction increases with depth, but not ... it is sometimes high around upper part and absent at bottom, so ... caisson is practically hung by the top. Severe tensile stresses may ... to resist which the successive masonry courses must be thoroughly ... and in deep caissons vertical reinforcement is also necessary. The ... p action is greatest when caisson cuts into running ground after ... a thick stratum of firm material.

... should be so constructed as to cut into the ground with minimum re... and to provide a firm base for the walls, so that "hanging up" of ... a boulder or irregular rock ledge will not seriously crack or damage ... 11 shows a common form of shoe, as used at Shaft 2, Rondout siphon ... 11. Fig 12 and 13 show other forms, in which the plates are con... through the wall by gusset stays and are bonded to masonry with ⅞-in ... bars. The latter may be extended to form the vertical reinforcement ... above, which, in any case, should be attached to shoe.

Excavation and sinking. Excavation within the caisson is done by hand, ... grange-peel or clam-shell grab bucket. The grab bucket is cheaper ... digging, though for a single shaft its cost, with the additional rigging ... handle it, outweighs the saving. But if the sinker owns, as part of ... equipment, a grab bucket with derrick and engine adapted to handle ... economical to install them rather than the lighter and cheaper equip... and work. Aside from cost, the character of the soil often determines

the method of excavation. An important point is to KEEP the CAISSO TICAL. In uniform ground this is done by excavating evenly around un shoe; in variable ground, when caisson deviates from vertical, it is recti cutting more material from under the shoe on the high side. When th strikes a boulder big enough to support the caisson, it must be remove fully to prevent an inrush (Art 2), or it is drilled and blasted into piece enough for the shoe to cut through. Thus, even when a grab bucket for most of the excavation, some hand work is necessary. When depth ting edge below bottom of excavation is less than width or diameter of deviation from vertical is easily corrected as stated above. At greater correction is difficult or impossible; but in this case the caisson is unli deviate, provided boulders are properly handled and inrushes of grou vented by keeping cutting edge well in advance. This is accomplished: starting with heavy caisson, having smooth outer skin and sharp cuttin

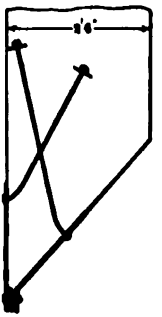

Fig 11 Roundout Caisson

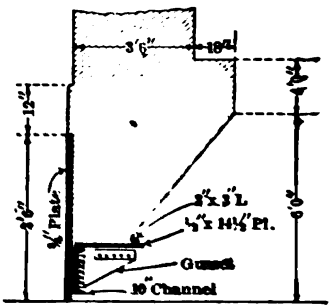

Fig 12. Colorado River Caisson

Fig 13

Cutting Edges of Shoes .All Rivets through Cutting Edges countersunk

) by weighting caisson; (c) by reducing skin friction. For extra w invert is best since a great weight can be piled on a relatively small top of caisson.

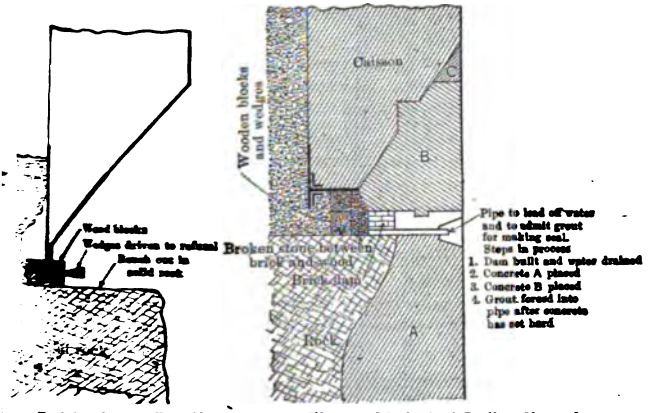
For deep caissons, extra weight should be provided for in the design Excavated material itself is the cheapest weight. Skin friction can sometim above by pumping air or water into the surrounding ground through holes (Example I, below), or by allowing the water to rise in caisson to balance a grab bucket being used for excavation under water. In latter case, since flow of water impedes it, are reduced and caisson is more readily lower the other hand, boulders are particularly troublesome and divers have sometimes required to remove them. Example III, below.

Sealing caisson to rock. When shoe reaches rock a permanent be made. This is done by [illegible] rock surface is level, so that cutting come to it over bearing [illegible] of rock is partly dissolved a depth of several inches. The disintegrated layer permits cutting and [illegible] it serving as a guard to exclude the sand. rock is hard, a tight joint can be made between shoe and rock by [illegible] sawdust will [illegible] and shape [illegible] will wonder wedges. Fig 14 having been wedged, rock excavation is commenced. As in sinking [illegible] the last rock cut should be [illegible] of diameter, a [illegible] to prevent [illegible] from breaking rock under cutting edge.

...ing may be done more freely, as there are no cross braces to be knocked ...

...en rock surface is sloping or irregular, and ground immediately over ...ad, the shoe may be rigidly supported at one point of its perimeter, the ...t being in soft ground. The caisson is thus thrown out of plumb, a con... which is aggravated by runs of soft material caused by attempts to break ...e rock under point of contact. This rock must be blasted and removed ...reat care, a little at a time, breast boards or short sheet piles being used ...k back adjacent soil.

...round be very soft, it may be necessary to support the free side of caisson on posts ...small sheeted pits driven to rock, and to hold back the ground temporarily by in... ...ding boards driven under flare of shoe. In this case the permanent seal is usually ...ructed as follows: The shaft is sunk 8 or 10 ft into solid rock, of a section as large



...Wedging for Sealing Shoe ...f Roundout Caisson

Fig 15. Method of Sealing Shoe of D, L & W Caisson

...ing above will permit, a small ledge being left to support the cutting edge, or ...s and sheet piles (Fig 15). All water coming in under shoe or through the piling ...at this ledge, and led through pipes to interior of shaft. A back form is con... from ledge to caisson, just inside cutting edge, and a concrete lining is built ...ft bottom to caisson. After concrete has set the drain pipes are plugged or ...with cement grout forced in under pressure (Art 7). Since the lining meets the ...order side of caisson it should be bonded to it with rods or bolts. If ground is ...t and rock surface irregular, the difficulties of founding and sealing the ... may be so great as to require use of compressed air to hold back the water (Art ...ergency to be considered in the design.

Examples

Shaft 2, Roundout siphon, Catskill aqueduct. The caisson for soft-ground por... ...shaft was cylindrical, 26 ft outside diam, walls 2 ft 6 in thick. Shoe (Fig 11) ...2 of 0.5 by 20-in steel plates, with 4 by 1-in filler at cutting edge, and was an... ...concrete by 80 ¾ by 30-in rods, attached alternately to inner and outer plates. ...consisted of 1 cement, 2 sand, 5 stone. Inner and outer forms were of 2 by 6-in ...wood lagging, supported by angle-iron rings tied through walls with ⅝-in rods. ...was built in 5- and 10-ft lifts to full depth of 55 ft, lifts being bonded together by ...vertical reinforcing rods, 4 ft c-c.

Finished shaft was 10 ft 8 in by 22 ft in clear. Borings showed 60 ft soft gro upper 6 ft being sandy loam, and the rest a material resembling blue clay when was completely saturated in place, flowing "like cold molasses and very stick bed rock, and surrounded by soft soil, were numerous hard boulders of all siz shaft site was leveled, shoe assembled upon short planks laid on ground, and forms started. 5 ft of concrete was placed and allowed to set for a week; 10 was then placed and when sufficiently set, sinking was begun. Mud was loa shaft buckets, sometimes with shovels, sometimes with water buckets, by men on plank rafts. Concrete was added as caisson sank. At a depth of 45 ft a laye

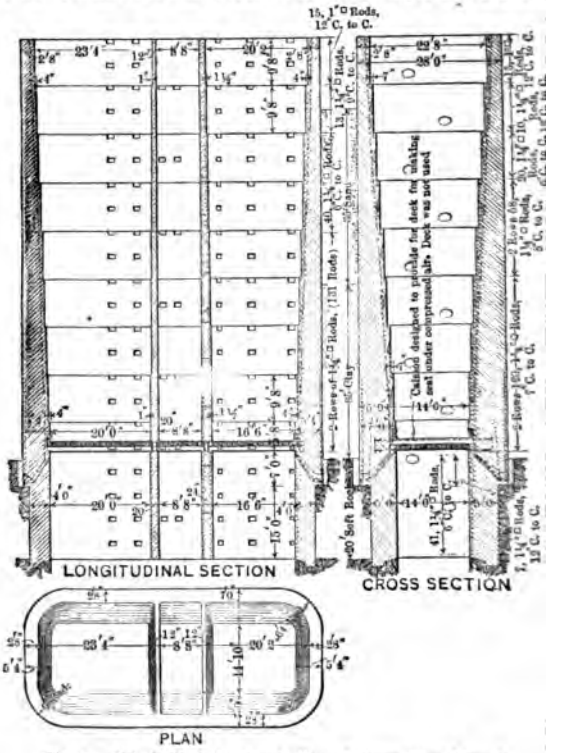


Fig 16. Del. Lack & Western Colliery Caisson (Eng News)

soft mud was encountered, which ran in under one side of shoe, throwing cai out of plumb. A trench was therefore dug through surface loam on high side o the material from it was piled against low side, and when sinking was resumed th straightened up. About 6 ft from rock, the shoe was stopped by boulders for lon time to allow mud to stick to caisson walls, so that after boulders were blast was necessary to load caisson with 200 tons of clay, and also to agitate the compressed air blown through 1.25-in pipes built into the wall. A layer of har found just over the rock, into which the cutting edge sank deep enough to seal son automatically. Average progress, from building shoe to sealing of caisson ft per day, including concreting and all delays. Cost per ft: concrete and s

...rating, $39; general expense, $32; total, $133. Before sinking was stopped by ... at depth of 50 ft, skin friction was less than 380 lb per sq ft; afterward, at same ... 500 lb.

Maximum skin friction was about 460 lb per sq ft, even when caisson was

4. Pneumatic Caissons

General design of pneumatic caissons is similar to that of open caissons ...cluding materials and construction; chief difference is in method of ... In the pneumatic caisson, an air-tight deck is constructed 7 or 8 ft ...e, and ground water is entirely excluded by maintaining under the ... air pressure equal to or greater than that of the water outside. A ...t is therefore required. Men are admitted to working chamber, and ...d materials removed, through one or more air locks fitted to openings ... General vertical section of a caisson is shown in Fig 17. ADVANTAGES: ... water is excluded and shaft bottom is held down by air pressure, in- ...der shoe are prevented, even in very fluid materials; (*b*) caisson may ... without "pulling in" surrounding soil, and hence may be kept con- ...vertical; (*c*) boulders or other obstructions under shoe can be removed

with greater ease and safety. DISADVANTAGES: (*a*) expensive air plant quired; (*b*) use of a grab bucket is precluded; (*c*) cost of hand excav is greatly increased; (*d*) po depth of sinking is limited to more than 100 ft below gr water level.

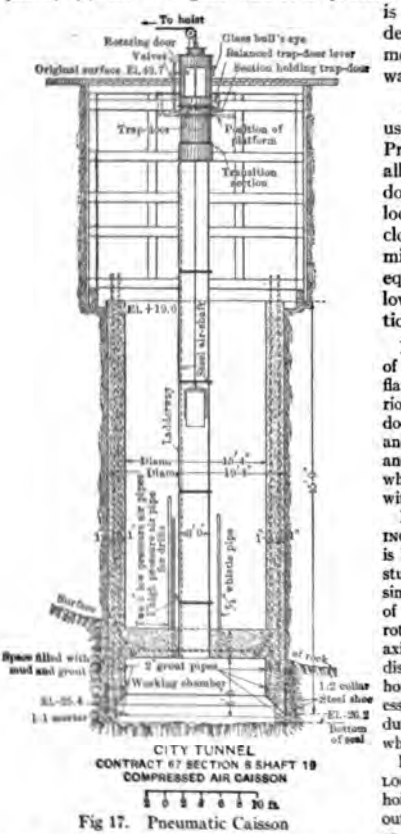

Fig 17. Pneumatic Caisson

Air locks of types most used are shown in Fig 18 Principle of operation is sa all: for admission to caisson, door is closed, upper one o lock is entered, and upper closed; compressed air is th mitted to lock until press equal to that in caisson, lower door is opened. The tion is reversed in passing o

Fig 18 shows a MAN LOCK, for of men only, and fitted with flap doors. It is controlled fro rior, the lock tender standing o door plate and manipulating air and lower door. Upper door is and closed by an assistant out whom lock tender signals by with a hammer.

Fig 19 shows a MATTSEN E ING LOCK, into which a muck is hoisted by a rope passing th stuffing box in top. Lower d simple flap; upper door is in t of lock and opens by sliding s rotating at same time about th axis. The bucket to be rem disconnected from rope and horizontally, and as this is a slo ess the bucket is usually arra dump its load of material into while hanging in the lock.

Fig 20 and 21 show STRAIGHT LOCKS, by which the bucket hoisted or lowered through caiss out detaching from rope. Lo on both are simple flaps. POT-U (Fig 20) has an upper door which can be entirely disconnected, the hoisting ro ing through a stuffing box in the middle. While bucket is in caisson, several manipulated swing bolts hold lid in place. Bolts are loosened after bucket is hoi lock, lower door is closed, and lid is then hoisted away with the bucket. M (Fig 21) obviates necessity of tightening and loosening bolts, and is therefore qu operate. Upper door is a simple flap, so located that when bucket is hanging free in the rope passes through a groove in upper door frame, just clearing edge of door. Th is fitted with a special stuffing box, so designed that, by rotating it 180°, it clasps o the rope. In operation the bucket is lowered into lock through upper door, and pushed sidewise until rope enters groove; stuffing box is rotated, upper door closed a opened, and bucket lowered into caisson. All excavating locks are operated from

Excavation and sinking. Material from caissons is usually sho hand into 30-in cylindrical buckets and hoisted through lock. If a sc

si compressed air be available, loose sand can be blown out through a SUCTION PIPE (Example I), by shoveling it into the end of a suction hose at- to pipe. The work itself is simple, the difficulties of the process being effects of compressed air upon laborers. Up to pressures of about 20 lb equivalent to depth of 46 ft below ground-water level), men can pass

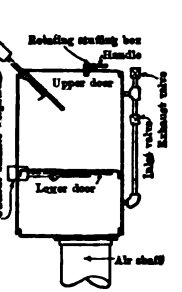

Fig 21. Moran Lock

lock in 4 or 5 min, and can work 8-hr shifts under pressure without in- but, as pressure increases above this point, the time of locking through must reased and length of shifts decreased, to avoid caisson workers' paralysis (Sec 15, Art 34.) Rate of wages also increases with air pressure. human endurance is about 50-lb pressure. Table 1 shows requirements York law governing caisson work, and wage scale in force in 1914:

Table 1. Requirements of New York Law for Caisson Work

Pressure, lb per sq in	Hours per shift		Wages per shift	Pressure	Minimum time of decompression
	Total	As worked			
				Up to 10 lb	1 min
10 to 21 lb	8	½ hr for lunch	$4.50	10 to 15 "	2 "
21 " 30 "	6	3 on, 2 off, 3 on	4.75	15 to 20 "	5 "
30 " 35 "	4	2 on, 4 off, 2 on	5.00	20 to 25 "	10 "
35 " 40 "	3	1.5 on, 4.5 off, 1.5 on	5.25	25 to 30 "	12 "
40 " 45 "	2	1 on, 5 off, 1 on	5.50	30 to 36 "	15 "
45 " 50 "	1.5	As arranged	5.50	36 to 40 "	20 "
	.....	.....	.....	40 to 50 "	25 "

Wages are increased 50¢ per shift on concrete work.

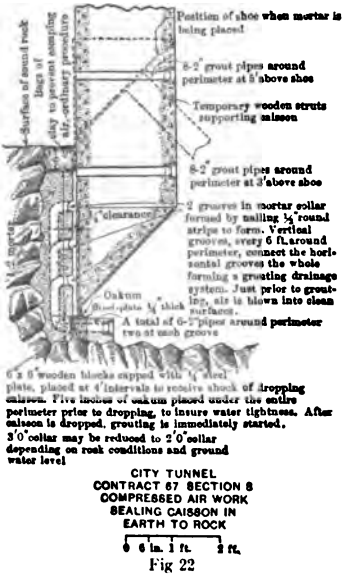
supply. Sufficient air must be pumped into caisson for adequate venti- Good practice requires 30 cu ft per min of free air per man. When less amount escapes in lockages and leakages, the remainder usually flows the shoe.

pressure required, theoretically, should suffice to balance hydrostatic ting at the level of working chamber, due to depth below water level. ead may be greater or less than depth below surface of soil. Pressure, sq in per ft head, is 0.433 lb in fresh water, 0.445 lb in sea water. If should pierce a stratum of stiff impervious clay, it might be possible t

reduce working pressure much below that theoretically required (as at hattan bridge, N Y), and thereby increase the attainable depth. To ma a vertical face of soil under the unsupported side of a caisson resting at ot on sloping or irregular bedrock, the pressure should correspond to the head on the face.

Weighting. In sinking pneumatic caissons, upward pressure of comp air must be overcome, as well as skin friction; hence, they are usually h per unit of horizontal area than open caissons. On other hand, the bu up of air escaping under shoe stirs up the ground and reduces its adhe caisson. Pneumatic caissons can easily be loaded by filling space over th between walls and air shaft, with excavated material; pig iron may b on top, if necessary. A sudden release of air pressure (the men having l working chamber) is an effective method of starting a stuck caisson.

Sealing to rock of a pneumatic caisson is similar to that of open c (Art 3), except that, instead of inflowing water, outflowing air must l



Position of shoe when mortar is being placed
8-2" grout pipes around perimeter at 8' above shoe
Temporary wooden struts supporting caisson
8-2" grout pipes around perimeter at 3' above shoe
2" grooves in mortar collar formed by nailing ½" round strips to form. Vertical grooves, every 6 ft. around perimeter, connect the horizontal grooves the whole forming a grouting drainage system. Just prior to grouting, air is blown into clean surfaces.
A total of 6-2" pipes around perimeter two at each groove
6" clearance
Oakum
6 x 8" wooden blocks capped with ½" steel plate, placed at 4' intervals to receive shock of dropping caisson. Five inches of oakum placed under the entire perimeter prior to dropping, to insure water tightness. After caisson is dropped, grouting is immediately started.
3'0" collar may be reduced to 2'0" collar depending on rock conditions and ground water level

Note.—All these caissons were weighted with excavated sand piled on top of deck ...over shafts. In each case, a pit was excavated and timbered square to depth of ... ft. The shoe was set on bottom, and caisson built to its full height before sinking ... started. Contract price allowed a fair profit to contractor.

Examples

1. **Shaft 19, N Y aqueduct** (Fig 17). For structural reasons not related to sinking, ... and horizontal reinforcement of concrete was made unusually heavy. The ... ckness of 2 ft, for a required inside diam of 15 ft 4 in, was at least 1 ft less than ... required for a caisson of same depth. The deck was a 3-ft slab of reinforced ... cast integral with caisson walls, and was cut out after seal was made. Ex... the concrete deck, the design was typical: a 36-in circular opening was provi...

in deck and a vertical line of 36-in flanged steel pipe (air shaft) was led from open top of caisson, where air lock was attached. Opening was formed by casting bottom of air shaft into the deck; (where deck is of wood or iron, the lower flange of air bolted to it). Air shaft was long enough to keep lock always above ground-water l that, in case of accident to lock or to air-compressing plant, the caisson men would trapped by rising water. Air shaft had ladder rungs so arranged as not to in with operation of bucket. Besides the air shaft, one or two 3-in inlet air pipes at bottom with check valves, a 0.75-in whistle (signal) pipe, a high-pressure air conduit for electric wires, and sometimes a 4- or 6-in discharge or "blow" pipe, through deck. In deeper caissons, 2 air shafts were provided, fitted respectively material lock and a man lock.

II. Kidder shaft, Cleveland-Cliffs Iron Co, Mich. Caisson was 24 ft diam (Fig 23). Air shaft, 10 ft diam, was used first as a dredging shaft for a cla bucket, which excavated to a depth of 87 ft. As it then became necessary to us pressed air, a deck and air lock were bolted to the top. Ledge rock was reac 104 ft. Shoe was sealed to rock at 113 ft. Average progress, 0.72 ft per day time.

5. Forced Drop-shafts

General description. For penetrating depths of quicksand and oth stable, water-bearing material, beyond the limit of open or pneumatic cai a method has been developed in Germany of jacking down a telescopic se iron drums, inside of and against a preliminary cylindrical concrete ca The latter is strong and heavy, and built into it, near the top, is an in cast-iron flange, the REACTION RING. This is anchored by vertical rods e ing to the shoe, for resisting thrust of the jacks, which are attached to an against under side of ring. The caisson is sunk by dredging in the ope depth of 50 or 60 ft; then a concrete floor, PLUG, is placed in the bottom (water if necessary), and shaft is unwatered. A cast-steel shoe, with an o diam slightly less than inside diam of caisson, is set on the concrete floor, cylindrical drum, of flanged and bolted cast-iron segments (similar to tubbing, Sec 7), is built up from shoe to under side of the jacks. The conc then broken, thus admitting water to natural level, and the drum is jacked the material being excavated under water by a grab bucket, mammoth or sack borer (described below). Finally, the jacks are removed and add segments of lining added as required. By using hydraulic jacks, a drum outside diam can usually be forced down 250 to 300 ft before it sticks. I lies still deeper, the bottom is again covered with concrete, the shaft watered, a second drum of smaller diameter is built inside the first, the are shifted inward to bear upon it, and sinking is resumed. Frequently a drum has been necessary; less often, a third (4).

Details of construction of caissons, drums and sinking plant are sh Fig 24 and 25. A headframe is provided to handle the machinery, whi cludes: trepans, similar to those used in the Kind-Chaudron boring meth rock (Sec 7), for breaking up the concrete floor and any boulders or par mented ground that may be met; the caisson, with reaction ring and hy jacks; and sinking drums. The outer drum (Fig 24) is the patented Pa compound, the cast-iron shell of which is lined with 22 in of strong brick crete, for additional weight and stiffness; the second is a simple iron-s drum. The compound drum is made necessary by the great earth pr at depths of 300 or 400 ft, a number of shafts having been lost by colla unsupported iron drums, notwithstanding use of segments 3.5 in thick. segments are about 5 ft high, flanged and bolted on both horizontal and v joints, and 8 to 10 of them make up a ring. The shoe must be very stro heavy, and anchor and reaction rings and all bolts must be designed to

safely the full thrust of the jacks. For considerable depths, the grab b used in ordinary caissons has been superseded by the mammoth pump in fi and the sack borer in softer, soils.

Mammoth pump (Fig 24) comprises the hollow rods of the trepan or b tool (through which water is pumped under pressure to cutting edge of tre in combination with an air-lift pump, the pipes of which are also attach boring rods. The suction opening of the pipes is at the middle of the tr just above its point. The trepan should make short rapid blows, to agitat broken fragments of ground, so that they may be more quickly sucked i discharged by the pump. As compared with the sack-borer, and other rot or dredging devices, the mammoth pump shows less tendency to deviate vertical direction.

Sack borer (Fig 25) is a large auger-like tool, with its stem in center of The stem is composed of a series of lengths of heavy flanged pipe, termi at upper end by a splined section, on which is mounted a large horizontal wheel. A wire rope, from hoisting engine drum to swivel link at top of suspends the sack borer. The stem is rotated through the gear-wheel b other engine, and is lowered gradually by hoisting rope. New sectio borer stem are added as shaft is deepened. Cross arms are attached t stem at intervals, having rollers at their ends which bear against sides of and keep stem in line. The material cut by rotating borer is swept int heavy, open-mouthed canvas sacks, fastened to backs of cutters. From to time the borer is raised and emptied. In an improved form, the sack mounted on a frame sliding on guides attached to cross arms on stem, an hoisted by an independent engine. The sack borer is best adapted to cla sand.

Sassenberg process of hydraulic flushing reduces skin friction and adhesion in soils. Shoe and 4 lining rings above it are made of about 1.5 in larger outside dia than the rest of the lining, and in the shoulder thus formed are water passages, whi connected through pipes to a high-pressure pump. By operating this pump sinking, the drum is partially surrounded by a film of water.

Examples

I. Shaft 5, Rheinpreussen colliery, Homburg am Rhein, Germany, was s in 1901 with a brick caisson 29.2 ft inside diam, walls about 3.5 ft thick. This rea depth of 65 ft. Concrete plug, 9 ft thick, was then placed on the bottom, under the shaft was pumped out, the anchor ring, rods and reaction ring (designed for a sure of 3 000 tons) were erected, and an inner, truly vertical, brick lining was reducing inside diam to 25.68 ft. A compound sinking drum with outer and inner of 25.52 and 21.32 ft respectively was then constructed, and sinking was begun percussion borer and mammoth pump. The concrete was bored through in 4 day thereafter the average progress was about 5 ft per day. The compound drum stuck ft, and shaft was filled for 60 ft with sand and gravel (instead of concrete). Sha next pumped out and an iron drum, 3.5 in thick and 19.35 ft inside diam, was bu to the jacks. This drum struck at 315 ft; the shaft was again partly filled and pu out, and another drum, 17.38 ft inside diam was forced to a depth of 343 ft, whe shoe entered clay firm enough to permit shaft to be pumped out. A fourth drum ft inside diam, was finally forced to the coal measures, at a depth of 508 ft. The si took 3 years, the average progress being about 6 in per day (4).

II. Sterkrade shaft, near Holten, Germany, was started with a brick c 24.6 ft inside diam, which was sunk to a depth of 59 ft. The excavation was cont by hand to 131 ft, where an iron sinking drum, 22 ft inside diam, was constructed. drum was forced to 264 ft; a second drum, 19.3 ft diam, to 433 ft; and a third, 16 diam, to 448 ft. Here the water was found to be successfully shut out, and sinkin continued by hand (4).

Table 3. Cost of Sterkrade Shaft

Brick curbing, 59 ft @ $285		$16 800
1st iron drum sunk 133 ft @ $502		
Segments	$32 900	
Labor and supplies	33 900	66 800
2d iron drum sunk 169 ft @ $715		
Segments	75 300	
Labor and supplies	45 900	121 200
3d iron drum sunk 15 ft @ $6 060		
Segments	71 500	
Labor and supplies	19 300	90 800
Depreciation of plant and fittings, 50% of new value		43 300
Total		$338 900
Less salvage on tubbing recovered from inner drums		35 700
Total cost for 376 ft		$303 200
Cost per ft		807

Average cost of sinking-drum method in Germany, at various depths, is given by Henry Louis, as follows:

Depth	Cost per ft
52 to 164 ft	$260
164 to 328 ft	593
328 to 492 ft	817
492 to 656 ft	1 040

6. Freezing Process

General principles. This process, invented by F. H. Poetsch in 1883, consists in solidifying soft watery ground by freezing, prior to excavation, so that the frozen ground itself makes a water-tight wall around the shaft, permitting safe excavation. Freezing is continued until rock is reached, after which the shaft is lined. A number of vertical holes are bored from 2 to 4 ft apart, in a circle outside the periphery of proposed shaft, and cased through the soft strata into rock. A freezing plant is erected, and the freezing solution is circulated down interior pipes and up through the bore-hole casings, until the surrounding ground is frozen solid. The process is adapted to soft ground or wet rock, and requires the material to be such that holes can be bored with reasonable ease and accuracy; ground water must also contain little salt in solution, and not be in active circulation. Strong circulation of ground water will hinder or may absolutely prevent freezing. The holes should be vertical, for a slight deviation may result in so wide a gap at bottom, between two adjacent pipes, as to prevent thorough freezing of the ground between them. To overcome this difficulty in sinking to great depths, freezing in successive lifts has been suggested. Some saline solutions freeze at a lower temperature than plain water, a leak or break in a freezing pipe is serious; the solution, by escaping into the surrounding soil, will cause a weak spot, if not a hole, in the frozen wall and make necessary a longer period of freezing. Furthermore, at great depths ice tends to flow under pressure, and the thickness of ice wall required to resist this tendency at a given depth must be studied. Frozen sand is much stronger than pure ice. Alby's experiments (23) show that frozen saturated sand crushes under 1 500 lb per sq in. at temperature of $-25°$ C, and at about 1 700 lb per sq in at $-12°$ C. It should therefore carry safely a pressure of about 300 lb per sq in, and assuming full hydrostatic pressure on outside of ice cylinder, the thickness of ice wall for a shaft 300 ft deep and 20 ft diam outside the permanent lining would need to be 7.5 ft.

Freezing tubes are sunk by methods ordinarily used for casing bo (Sec 9); in soft ground by washing the material up inside casing by water forced down a smaller interior pipe (with occasional use of sand and in hard ground by drilling with a percussion well drill, the casin forced or hammered down in both cases. The holes should be surveye time to time, so that one with too great a deviation may be abandoned, new hole started. Absolute verticality is impossible; good practice lim deviation to not over 3 ft in 300 ft. (Holes are surveyed by method in Sec 9.) Difficulties caused by breaking of casin to temperature stresses during freezing, make it ad to use independent freezing tubes. Fig 26 shows used at Dawdon colliery, Durham, England, in 1902 4-in heavy pipe, with its lower end welded shut, is l into the 6-in bore-hole casing, tested hydraulicall casing is then withdrawn. The freezing solution is p down through the 1-in interior pipe and returns t the other. The inner and outer pipes are connec headers as shown, valves being provided to regulat of solution and cut out any hole quickly, in case o age.

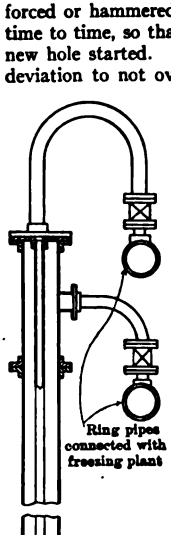

Fig 26. Freezing Pipes, Dawdon Colliery, England

Freezing plant and freezing. Ammonia compr freezing plants are generally used, the Linde type of m being particularly satisfactory. The freezing soluti brine, is chilled by the expansion of compressed am gas, and is then circulated through the freezing pip magnesium chloride solution is recommended, as th has less tendency to precipitate at low temperature the calcium chloride commonly used in ice plants, and is consequently less danger of clogging the pipes. required capacity for a given shaft may be worke theoretically, but good European practice prescri capacity of from 1 to 2 tons of ice per hr for dep 200 to 300 ft, and a freezing period of 3 to 5 month a rough approximation, 1 ton of ice per hr requires at compressor engine. The total hp of different plant ranged from 50 to 250. The condition of the ground being frozen is indicated by temperatures of inflowin returning brine. The brine leaves machine at a temper of about $-20°$ C, and at first returns comparatively w As the measures become frozen, the temperature of the re ing fluid drops until the difference is only $2°$ or $3°$ C, excavation can be safely begun. Throughout excavatio freezing plant must operate at full speed, to maintain t wall against thawing by circulation of warm air in the s

Sinking, after freezing, is done by hand. It is usually necessary to blast the f sand with light charges; black powder, gelignite, and dynamite having been used cessfully. Care must be taken not to crack the frozen wall, for the smallest leak is tain to enlarge itself by thawing until a disastrous inrush may occur. Presence of in a drill hole signifies that the soil is insufficiently frozen, and sinking should be sto

adly near the bottom, new holes must be kes necessary a longer freezing period.

III. Chapin shaft, Iron Mountain, Mich (10), was sunk in 1888–9, throug sand, gravel and boulders, with water level 10 ft below surface. Twenty-six 10-i pipes were put down in a 29-ft circle; inside of these were 8-in freezing pipes, i 1.5-in circulating tubes. Casings were then withdrawn. Ice machine was a (ammonia type) of 50 tons daily refrigerating capacity (1 ton equals cooling effect melting ice). Freezing fluid was saturated solution of commercial $CaCl_2$; vel flow in the 1.5-in pipes, 2 ft per sec. In about 21 days after starting ice mach frozen ring was complete and excavation was begun. Rock was reached in 1 (including a 30-day stoppage, when shaft was allowed to fill with water). Th some trouble and delay from leakages through ice wall, the entire elapsed time, to at rock, being about 200 days.

7. Grouting Process (for rock)

Characteristics. The general principle of solidifying water-bearing in advance of sinking, accomplished in soft ground by freezing, is app hard rock by injection of Portland cement grout into the fissures; the gr process was used for this purpose in France, as early as 1882. It has sinc used many times with entire success (13), is rapidly gaining favor, and is recognized as the cheapest method of sinking in wet rock.

The advantages of completely stopping, or limiting the flow of water into a sh great: pumps and piping are reduced, fewer boilers are required, and operating cos throughout. Against this saving must be placed the cost of the cement and time o in grouting. In case of a fissure with a comparatively small flow, say 100 gal per m depth of 100 ft, with ordinary boilers and sinking pumps, and coal at $3 per ton, cost alone for pumping will amount to about $70 per month. Such a fissure would pr not require more than 100 bbl cement, which at $2 per bbl would be paid for in 3 by saving in coal. The cost of hindrance to sinking cannot be stated definitely, b flow of 500 or 600 gal per min into the bottom of a shaft will usually reduce rate of to one-fourth of that in a dry shaft, it would appear that three-fourths of the tot could be profitably spent in grouting, provided it were necessary to keep the sha Grouting is difficult in water-bearing fissures carrying sand or mud (Example I, and is not applicable to soft ground. Two common variations are practiced:

(*a*) Deep-hole method, the purpose of which is to fill the fissures in one operat a considerable depth of water-bearing rock; (*b*) short-hole method, by which fissu treated successively as they are reached. The former has been used in Europ number of instances; the second is becoming common American practice.

Deep-hole method. A number of holes are drilled through the fis ground, either inside or outside the proposed shaft periphery, pipes are nected to them and grout is poured or forced from surface until the holes to admit more. Operation of injecting is begun at bottom of holes, the gro pipes being withdrawn by stages, as fast as fissures are filled. To aid lation of grout, a second series of holes may be drilled outside the grout and suction pumps attached to them, thus removing from the fissures all or other materials likely to clog the grout holes. The holes should be bored a core drill, rather than a percussion drill, as operation of the latter is lik obstruct fissure with cuttings. When hole is completed, rapid pumping its bottom for several hours will remove refuse from rock crevices.

Short-hole method. The same holes drilled for blasting are used for g ing, if they cut into a water-bearing fissure; grout is forced in by a pneu grout tank. The Canniff tank and mixer (Fig 27) is a cylinder 18 in dia 3 ft long, with a door on top through which cement, sand, and water introduced, a 2-in discharge opening at bottom, closed by a stop cock, an connections top and bottom, each controlled by a valve.

Mode of procedure. Grout connection pipes are first prepared, each consistin 3-ft piece of 2- or 2.5-in pipe, tapering gradually to 1.5- or 2-in diam at one end, thre and fitted with a heavy iron stopcock at other end. When a drill hole cuts a water- ing seam, drill is withdrawn and one of the pipes is driven into it, the tapered end

to make a watertight joint. Stopcock is after pipe is firmly sealed. After all flow-

II. Lens Mining Co, France (13), sunk a shaft by direct cementation in Ordinary sinking, with pumping, carried depth to 126 ft before the inflow becan great to handle. Grout pipes were then inserted in fissures, and shaft allowed with water. Four 8-in holes, 13 ft outside the shaft, were bored through the fi ground, and sludge pumps were attached to them. Cement grout was run into th ices from a mixer at surface, and at the same time mud and water were pumped the bore holes, to assist grout to penetrate. Injection of 500 bbl cement sealed the f sufficiently to permit shaft to be sunk to solid rock at 492 ft. The cost was:

Installation of plant, etc	$12 800
Pumps	5 040
Cement	1 550
Labor, sinking and lining	21 770
Tubbing (material only)	17 100
Total	$58 260
Cost per ft for total depth	118.30

Operation. A pipe of the required diam is sunk, the core is broken up by a jet of water, or, if necessary, by a chisel bit, and the disintegrated material is brought to surface by the current of water. For penetrating SOFT GROUND, a smaller pipe carrying water under pressure is worked ahead inside the drivepipe as fast as the loosened stuff is carried to surface. In such material the drivepipe sinks of its own weight, or can be made to do so by rotating it by cross-bars (brace head), weighted by old carwheels, if necessary. In HARDER MATERIAL, a chisel bit is attached to lower end of wash pipe, and churned up and down to cut a hole below the drivepipe. Cuttings are washed to surface by a stream of water issuing from holes in the sides of bit. In this case the rig shown in Fig 2 is used, ropes *A* and *B* passing through a double block in the derrick. In GRAVELS the fine material is washed out, leaving coarser pebbles in the hole. If small enough, these are bailed out with a sand pump. If too large, they are broken with a cross chopping bit before pumping. BOULDERS are drilled through ahead of the casing, then broken with dynamite. The charge, made up for electric firing, is lowered to the proper depth by the leading wires. Before shooting, the casing is raised several feet to prevent injury. After shooting, casing can usually be driven through the broken rock. For testing overburden 2.5-in drivepipe and 0.5 or 0.75-in water pipe for drill rods are common sizes.

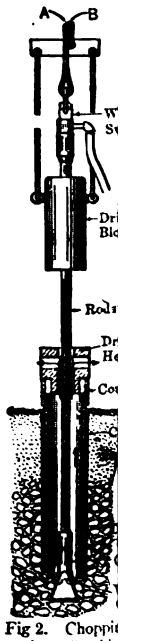

Fig 2. Choppi in Combi with Drive

For deep holes or holes in bad ground, several strings of pipe may have to be sunk, before reaching bedrock. This contingency must be allowed for in sinking diamond-drill standpipe, as the last pipe must be enough for the diamond bit (Fig 50). Minimum size of standpipe for diamond dr

oles have been started with 18-in pipe at
boring, but cost increases rapidly with

work done by one of these outfits in favorable circumstances. A similar outfit w
in prospecting residual iron deposits at Moa and Mayari, Cuba. B. Halberst
a similar outfit for coal prospecting, costing about $25.

At Toronto, Can, in similar work, the cost of 30 to 70-ft holes with labor at $2 p
was 29 to 55¢ per ft, respectively in clay and made ground. Supplies and bla
repairs comprised 15% of total cost per ft.

E. Low states (2) that boring 450 6-in holes, averaging 13.26 ft deep, with pod
in earth, clay, sand, and gravel, 3 men to a crew, the aver progress was 40 ft p
length of moves 200 ft; cost about 18¢ per ft.

Post-hole diggers are used alone or in connection with earth augers.

New Market Zinc Co, Tenn, used an ordinary post-hole digger for prospecting a
of zinc carbonate and silicate, in tough, residual dolomite clay, 10 to 75 ft thick
strap by which the handle was attached to the cutting blade was reinforced. Upp
of handle was threaded and attached to a 10 or 12-ft piece of 1-in gas pipe, making
handle. From a ring at upper end of gas pipe a rope passed over the pulley in an or
3-leg derrick, by means of which the digger was churned. In ordinary soil half-a
drops filled the tool, which will extract 3 or 4-in lumps of ore. Boulders were bro
dynamite and then churned up. Two men made 20 to 40 ft per day.

3. Spring-pole Rig. Hand Churn Drill

Spring-pole rig is a primitive form of churn drill, useful where fuel and
are scarce, transportation difficult, labor cheap, and where few holes are

of low first cost, maintenance, and ill in cost per ft of hole.

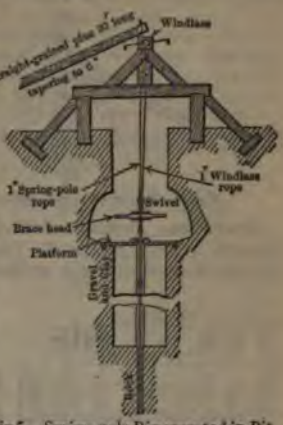

Fig 5. Spring-pole Rig operated in Pit

long; 1 iron-bound oak pipe driver, 4 ft 2-in drivepipe, 1, 2, 3, 4 and 5 ft long; d and 1 driveshoe; 1 pipe lift; 1 chain ch for pipe 5 in outside diam; 1 alligator ch for pipe 5 in outside diam; 2 screwjacks osening casing; 2 clamps for holding and g pipe with jacks; 1 rod 1 ft 8 in, 1 rod 8 in and 1 rod 5 ft 8 in between shoulders; ds 11 ft 8 in between shoulders (all rods or 1.5-in round iron, with 1.25-in square on near joints). 6 3-in drills, of 2-in octa- steel; 2 swivels, for windlass and spring- ropes; 1 brace head; 1 reamer; 1 foot ch; 1 hand or disconnecting wrench; 1 sand p for light drillings and 1 for coarse or pasty ings; 1 grab for drills and rods; 1 grab for p; 2 water barrels; black oil for rod and joints; blacksmith's and pipe fitting and ading tools; carpenter's tools. Fig 6 shows ral of the tools used. Cost of a rig for 250 ft not exceed $400 (3).

peed of drilling varies with size and th of hole.

shales and soft sandstones, 1.5 and 2-in s, 8 to 10 ft per shift for first 100 ft, and 8 ft for second hundred, are fair averages. he same rocks 3-in holes will advance 7 to per shift for the first 100 ft and 4 to 5 ft for nd hundred.

Hand churn drill is used for prospect- nber of holes to be drilled, or inaccessi- the portable power churn drill (Art 7).

Cost and speed. C. M. Rolker, prospecting on ISLAND OF BANKA in toug 11 to 32 ft deep, with raw crew, 4 men on platform and 6 on ground, averaged ft of 3.5-in hole per hr. Actual boring occupied only 8 to 30% of total time

Following is a record of work done in COLOMBIA, S A, in a jungle where could not be used. Day 1 : Moved across river and made 14 ft in top soil a gravel. Day 2: Finished hole 1, 2.5 ft to bedrock, 27.5 ft total depth. Pulled moved 100 ft before noon. Sunk 17 ft to bedrock in 4 hr. Pulled casing and moved to hole 3 and made 9 ft in overburden. Day 3: Finished hole 3, 24 ft total depth. Pulled casing and started hole 4 by 2 p m. Drilled 12 ft overburden and 10 ft sand and gravel by 5 p m. Day 4: Finished hole 4, total depth 28 ft to bedrock. Pulled casing, moved 300 ft to hole 5 and started by noon. Made 22 ft by 5 p m, passing through buried tree. Day 5: Finished hole 5 to 28 ft. Pulled casing and began hole 6. Made 14 ft in overburden and 9 ft in gravel. Day 6: Finished hole 6, to depth of 32 ft. Moved across and 1 mile up river and at 2:45 p m started hole 7. Made 6 ft in overburden and 9 ft in gravel. Day 7: Finished hole 7, total depth 29 ft. Moved 50 ft, sunk hole 8, 22 ft to rock. Started hole 9 after 50-ft move and made 6 ft in top soil. Summary: 7 days; 213.5 ft drilled; 30.5 ft per day.

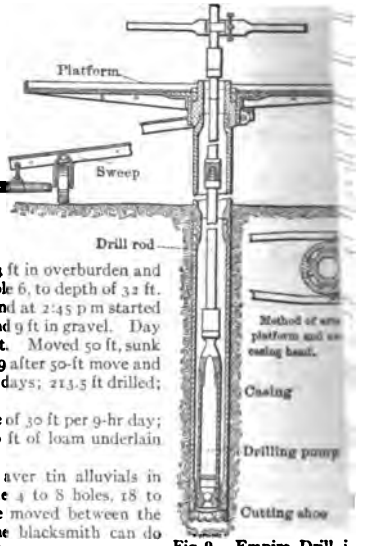

Fig 9. Empire Drill i ation

J. Chisholm reports aver advance of 30 ft per 9-hr day; 5 to 30-ft holes; 6-in drill; 9 to 10 ft of loam underlain by gravel.

E. Middleburg reports that, in aver tin alluvials in Banka, native crews of 8 men make 4 to 8 holes, 18 to 30 ft deep, in 8 hr, when distance moved between the holes does not exceed 60 ft. One blacksmith can do repairs and sharpening for 8 outfits.

R. E. Smith and H. G. Hann (4) give the following figures on work with two 4-in Empire drills in Siberia, when the thermometer re 0° to −45° F. Total depth, 6 696 ft; total time, 193.5 days. Percent total time 81.1, as follows: drilling, 63.7; putting on pipe, 2.9; pulling pipe, 5.0; clearing sn brush, 1.8; moving from hole to hole, 2.8 (aver time, 17 min); moving from line t holes over distance 6 083 ft (aver time per move, 2 hr 5 min), 3.1; lost time while 1.8. Percent total time lost, 18.9, as follows: moving camp (twice), 1.8; storm holidays, 5.2; resting screws, 3.1. Crew of 7 men on each drill. Aver time p 8 hr 20 min. Aver advance per hr of total time per drill, 2.1 ft.

CHURN DRILLING

5. Oil-well Rig and Its Modifications

Early forms of drills employed solid rods between the bit and surface anism. But, in deep holes, the weight to be lifted becomes excessive, wit bility to buckling or breakage of the rods on striking the blow. To pr this difficulty numerous free-fall mechanisms have been introduced in E such as those of Dru, Kind and Fabian, by which the rods are kept alw tension and the striking weight is constant (5). In America, developmer followed 3 lines: (*a*) substitution of a cable for the metal rods; (*b*) use o ing link or jars between rod and bit; (*c*) use of wooden rods. The first t these features are found in the standard rig; the third, in the Canadian rig

Rope socket	2.5 to 4	2.75 to 6	40 to 350	bit

Derrick is high enough to allow string of tools to swing clear of hole. Standard height, from top of sills to under side of crown block, is now from 72 to 84 ft. Base is generally 20 ft square.

Load on drilling cable, under ordinary conditions, is that of the string of tools, or a string of casing. Possible max load on the derrick is twice the ultimate strength of drilling cable. This load must be distributed evenly by the crown block to the derrick legs. Fig 12 gives sizes for the important timbers in an 84-ft, spike-joint derrick. Other designs by the oil-well supply houses are built of bolted wooden members, gas pipe or structural steel. These derricks can be set up and dismantled with little, if any, destruction of material, and in less time than the spiked derrick.

Fig 12. Method of pending Drilling R

Hoisting and transmission machinery. Bandwheel shaft, which distributes the power, is actuated by belt from the engine pulley to the bandwheel. From it the bullwheel is driven by a crossed rope running in grooved pulleys, the sandreel is driven by friction from the bandwheel, and the walking beam is actuated through crank, wristpin and pitman. Bullwheel carries drilling cable and casing line. It is thrown out by throwing off its crossed driving rope. When not connected with the engine it is controlled by a band brake. Sandreel is used to run the bailer in and out of the hole. When the sandreel is pulled forward, the friction pulley engages the bandwheel and bailer is hoi

tools are withdrawn and conductor pipe is lowered into hole and seated firmly in rock vent subsequent entry of surface soil. If soil caves, conductor must be driven ahea

Driving pipe. A shallow hole is excavated and in it is placed th length of drivepipe with a driveshoe on lower end and drivehead on upp The pipe is plumbed and earth filled in around it. Driving i by a drive block running in guides in the derrick or, more com by means of drive clamps (Fig 8) bolted to a square on the Weight is raised and dropped by either of the methods de under Spudding. When the pipe has been driven to refusal th is churned up and hole bailed out. Additional lengths are to the pipe as necessary.

Fig 19. Spudding Bit for Rock

Drilling. After the hole has been spudded to such depth there is about 100 ft of cable in the hole, the walking beam is br into play. The drilling cable is wound onto the bull-wheel, pitman connected with one of the inner holes on crankshaft, temperscrew hung on forward end of walking beam, the tools rested on bottom of hole, and the cable let out until there is about 4 in slack in the jars. The cable is wound with marline at the point where the temperscrew clamps grip it, temperscrew is clamped on, and the bullwheel slacked off, thus transferring the weight to the walking beam. About 25 ft of cable is run off the bullwheel and thrown on the floor to prevent lashing. On starting engine, the tools are picked up with a shock as the links of the jars come together, thus preventing the bit from sticking in the hole. Downward stroke of the string of tools is quicker than the movement of the end of the walking beam, because of the spring in the cable, action of the tools being that of a weight suspended by an elastic cord.

As hole deepens, the bit is fed downward by the temperscrew. For the first 200 ft or so the cable is twisted to keep the hole round. Beyond this depth, the twist in the cable itself is sufficient to bring the bit to a new seat at each stroke. When temperscrew has run out, it will usually be advisable to pump out the cuttings. Slack of the drilling cable is taken up on bullwheel, temperscrew clamps loosened, temperscrew run back, pitman thrown off the wristpin, and rear end of walking beam lowered. Tools are hoisted, swung to one side, and the bailer run in. After hole is pumped out, the tools are again lowered, attached to walking beam, and drilling is resumed.

Fig 20. tail B

Casing the hole presents varied problems. In hard rock that stands well, the only casing necessary is the lining for the finished well; this is put in after drilling is completed. Casing block hung in the derrick and the casing line run onto the bull-w A casing shoe is screwed on the lower end of a length of pipe, a coupling on the other end, an ELEVATOR (Fig 21) is locked ar the pipe below the coupling and the casing lowered through a RING or SPIDER (Fig 22), resting on the conductor, until only a few inches project. Slips are then dropped into the pipe ring, the elevator is unlocked, and another length picked up on the casing line and swung into place. This length is screwed into the projecting coupling and tightened by chain tongs. Casing clamps are then loosened and the string lowered by the bullwheel brake. This opera is repeated until the full string is in the well.

2.5 or 3 in diam, about 18

Two poles, joined by straps and fitted at ends with taper-box and pin-joints, for about 36 ft long. String of tools is the same as that of the standard rig. Cana can be dismantled and moved more rapidly than the standard, and pole tools are tageous for fishing; but it is now rarely used except for shallow wells, where frequen are necessary.

6. Speed and Cost of Oil-well Drilling

Controlling factors: (*a*) character of formation to be penetrated a vious knowledge concerning it; (*b*) depth and diam of hole; (*c*) type a of rig and weight of tools; (*d*) cost of fuel, water, and drilling supplies; (pose of hole; (*f*) general considerations, as location, experience of driller, number of shifts per 24 hr, climate, and accidents, discussed under D Drilling. Character of the formation affects speed of advance, and det amount of casing necessary. If much water is present, the buoyant lessens force of the falling tools, and in an oil or gas well the water n excluded. The pioneer wells in any district are drilled more slowly, an cost more than the later wells. Character of formation and depth of being unknown, it is difficult to choose the rig best suited to the work depth to which casing of a given size must be carried, to bottom the the desired diam is unknown, and the progress of the hole must be wat

General considerations. Cable rigs drill faster than pole rigs, bec the time saved in handling tools and pumping out the hole.

R. N. Boyd gives following data for a 1 542-ft well in Galicia, using Canadian rig ing rods, 25 min; letting down sand pump with rods, 14 min; drawing up sand 24 min; changing bit, 3 min; letting down bit, 14 min; connecting to beam, total, 85 min. Using a sandline for the bailer, the time can be reduced to 55 min. operations, with a cable rig to 1 600 ft, consume about 20 min.

Comparative speeds with California and standard rigs in the same for are less important than the fact that with California rig in a caving for the casing may be moved instantly, thus preventing an expensive cave o ing of the casing. This is impossible with standard rig. Heavy rigs an increase speed of drilling and of handling casing. For deep holes t creased speed more than offsets the greater time, labor and money invo erection. In established oil fields, the prices of natural gas or crude o for fuel vary so greatly as to vitiate cost estimates. Where coal must b 3.5 to 10 lb per hr per boiler h p is generally sufficient. Water may cos than fuel. In the California fields, where water at the well has cost as as 1¢ per gal, the daily water charge is $3 to $10. Cost of drilling suppli depreciation on the rig depend on depth of hole and character of servic deep holes, where the service is hard, there is almost no salvage.

Requa gives following figures for DEPRE-, aver time 88 days: bullwheel, bandwheel, ing in excess of water string, 60%; drill

shallow, due to greater time required out of the well, fewer strokes per min, ng. Large diam holes cost more than g. Superintendence	1 200	600
Supplies, material, additional labor	5 210 (*b*)	995 (*f*)
Total	16 380	2 860
Cost per ft	$1.96	$1.90

(*a*) Includes about 15 shifts. (*b*) Includes $200 drill. No rent or deprec on company drills. (*c*) shifts. (*d*) Driller at $4; panner at $3.50; fire $3; team and teamster at 9-hr shifts. (*e*) Driller panner at $3.50; fireman teamster at $2.50; all 9-hr (*f*) Includes team at les $2.50 per day.

Notes on drilling costs. The cost $1.90 to $1.96 at Natoma is somewhat lowe the aver for California. N. C. Stines gives 12 to 40 ft per shift as reasonable ress, cost per ft ranging from $1.40 to $3.50; $2.50 a fair average. D'Arcy Weat gives costs per ft for Oroville, Cal: 13 holes at $3.48, 7 holes at $2.50; for 5 holes, average depth 93 ft, aver cost, $3.85, winter rains, heavy roads, slow repai high fixed costs; for South Oroville, 50 holes, 35 ft average depth, $0.97 aver cost summer, all conditions favorable, 2 drills under one foreman and panner; for Or 9 holes, total 258 ft, 1 machine, 33 days single shift plus 4 for moving. He takes per ft as a fair aver for Cal work. J. E. Dick (12) gives $2.50 per ft as aver fo and about the same for Colo. J. P. Hutchins, writing in favor of hand dri prospecting in cold and tropical climates, gives daily cost of a steam drill in A in 1907, as $59 to $91 per shift. He sets 15 ft per shift as a good rate in gravel, using pipe; 50 ft or more in frozen ground without drivepipe, making a cost per foot of $4 to $6. T. A. Rickard cites 40 holes, 25 ft deep drilled in Alaska in August, for $1.01 per ft, including all costs, with wages as follows: driller $8, panner $6, fi

Rock, slate. Diameter of bit, 6 in.

At the New Haven Trap Rock Co's quarry, Keystone drills putting in 30-ft bl do not average more than 10 ft per shift. They make as high as 25 or 30 ft under exceptionally favorable conditions, but vertical cracks in the rock cause delays and lost holes that average is greatly reduced. One drill broke 4 stems in

ROTARY DRILLS

9. Rotary Hydraulic Drill

Construction and operation. With this drill, for boring in soft rock, r is loosened by a rotating bit on a line of drill pipe. Cuttings are ca surface by an upward current of water which is pumped down through p

Surface rig (Fig 40) consists of a derrick, 72, 88 or 106 ft high, similar to standard (Art 5); rotary-table *A*; draw-works *B*; engine *C*; and 2 pumps *D*. *A* is provided w for turning the drill stem, while allowing free vertical motion. It is driven by be and clutch on a horizontal shaft; which, in turn, is driven by chain from a sproc counter-shaft in derrick. Counter-shaft carries other sprockets, to take power fro and operate hoisting drum. Pumps are usually 10 by 5 by 12-in duplex, fitted for l heavy mud and cement grout at pressures up to several hundred lb. Typical borin naming parts from bottom upward, comprises: 8¼-in fishtail bit (Fig 41); couplin nect bit with drill pipe; a length of 6-in pipe; reducing coupling; 4-in drill pipe to drill stem; water swivel. When pipe is drawn from hole, joints are broken every 100 ft, according to height of derrick; at these points tool joints (Fig 42) are ins save wear on pipe. For drilling through thin layers of hard rock, Sharp & Hu (Fig 43) is used. For thick strata of hard rock, combination rig (Fig 44) is em

Speed of rotary drilling in soft formations has reached 1 000 ft per In such ground it is always faster than with standard rig. But, in ha

STANFORD LIBRARIES

differences in hardness of rock, and of presence of thin seams and small crevices. T mation is often invaluable when the core is much broken and its record cons incomplete. But, in strata of frequently varying hardness, it is necessary to run soft strata at reduced speed, so that the bit may not be damaged on meeting a h tum. With hydraulic feed the pressure is constant, and rate of advance varies less automatically as hardness of the rock varies. Thus, danger to the bit in pass soft to hard rock is lessened. The runner of the hydraulic-feed drill can instan advantage of changes in the formation, varying the rate of advance, within t imposed by the rock, merely by turning a valve. Three different speeds are with screw feed, unless the operator stops to change gears.

Hoisting drum (*B*, Fig 51) in small power drills is driven directly by gearing fro shaft. In the larger machine illustrated, it is direct-driven for light loads; but holes, when the weight of rod may be several tons, a compound gear reduction is The gears are thrown in by lever *F* when hoisting, and thrown out when drilling Hoist should have the greatest speed possible without endangering the diamonds machines have 2 band brakes, operated by levers *G*; small machines, 1 brake.

Engine (*C*, Fig 51) is double-cylinder, vertical, balanced, with quartering Diamond drill engines must be compact, smooth-running, and without dead They are fitted to run by compressed air when necessary.

Boilers. Two types of portable boiler are used, vertical and horizontal tubul horizontal is best adapted to mounting on wheels and is more conveniently tra over good roads. For transport in rugged, wooded, or swampy country, the type is better.

Pump. A duplex, boiler feed pump is generally used to furnish water to r hydraulic cylinder. It must give a steady supply at constant pressure, and be handle gritty water. Pumps wit lined cylinders and brass pistons and fittings are good.

STANFORD LIBRARIES

Drilling. Following is the normal sequence of operations:

Slide or swing feed mechanism away from hole. Set safety clamp in pos standpipe. Connect up bit, core shell (with core lifter), core barrel, and 1 leng and lower through the safety clamp until only a few inches project; then g clamps. Screw hoisting swivel into upper end of a section of rods, swing rods with the hoist and screw them into the joint projecting from the hole. L clamp and lower the string on the hoist brake until only a few inches project Tighten the safety clamp, and unscrew the hoisting swivel. Repeat these operat within a rod length of bottom. Bring feed mechanism back into place. Att swivel and lifting bail to the last length; lower it through the drive rod, and into place. Run the feed to highest position, and tighten the chuck. Loos clamp. Connect water swivel to pump and start the pump. Start drill and r ward until pressure shows that bit is against rock. While drilling, adjust feed sary. When measurement of rod indicates that core barrel is full, or laboring and engine suggest that it is blocked by broken pieces of core, stop the drill. K running until water issuing from hole shows that sludge has been well removed rods by reversing the operations of lowering. Extract core, and place it in co Change bit often enough to prevent diam of hole from falling below gage, and against loss of diamonds from wear of the metal surrounding them.

Casing or cement grout is used to support the walls of a diamond d when they cave so as to prevent progress or vitiate samples. CASING is flu tubing large enough to al bit to pass. Table 35 giv sizes of casing. If the hol tinued of same diam below ing ground, it is reamed ou the casing is introduced. mond drill holes are never s casing is a difficult operatio ing is usually twisted and down. Sometimes a "casi set with a few diamond c placed on lower end of the which is then operated as in drilling. CEMENT GROUT i and more used instead of casing. In badly caving ground the drill is driven as is safe, and the core and sludge saved. Then the grout is pumped do rods or lowered in a bailer. After it has set, the resulting "plug" is through, and a deeper section of hole is sampled and grouted. Quick cements are used, provided they are strong enough to support the hole. A 0.33% soda to ordinary cement shortens the time of setting to 24 to 36 hr.

Cementing is usually cheaper than casing, and allows the hole to be started at a diam without considering possible future support. In shattered ground the rods ma to be pulled frequently, on account of blocking of the core barrel. In soft ground if core is desired, frequent withdrawal is necessary or a double core barrel must be In fissured ground, part or all of the water will be lost. If there is standing water in fi strata, the sludge will deposit in crevices close to the drill, and re-enter the hole when current stops. Hence, water must be pumped through the rods during hoisting, an rods must be flushed down in lowering. Bran, sawdust, manure, or cement, are pu down the hole in an attempt to stop the crevices.

Accidents. Fishing. Commonest accident is LOSS OF BREAKAGE OF A DIAMOND (A Usual mode of recovery is to send down an old bit, the end of which has been filled wax. The diamond imbeds itself in this and is brought to surface. When the cannot be cleaned to the bottom, for using the waxed bit, a lost diamond may some be recovered by the bailer. The following device was used in such a case: A scree placed in top of core barrel and a screen clack valve set in an old bit, which was scr

rods were lowered through a stuffing box and the water current g the lost diamond was washed into the core barrel and held

may be due to fracture, stripping of threads, or unscrewing. t is usually a simple matter to screw them together again. reak, a recovery tap (threaded inside or outside according ered on a line of rods and manipulated until it engages the are similarly treated. JAMMING OF RODS may be due to cing with worn bit, or to too little clearance between rods ally gives some warning, but the required casing or grout- for progress. Jamming from a sudden cave can sometimes ing back the feed without stopping the engine, meantime ush will not often occur while pump is running. If the he rods all the way to the bottom, and kept running while danger zone, jamming will not occur. Pulling jammed essary, is destructive. The rods are seriously elongated, the threads may be partly or wholly stripped.

elow the core barrel, is a baffling and serious accident. a recovery tap, or some especially designed tool. Diffi- s from the fact that the bit may lie on its side; further- to turning, and therefore may turn with the tap. Bits he hole to a size allowing use of a bit large enough to bit. If the lost part cannot be recovered, the hole is it and continued (see Art 17, Deflecting boreholes). ten a serious factor in drilling.

ond drill consists of a runner and one or more e a good mechanic, since he must make most of e had long experience in diamond drilling. By ine, pump, and rods, a good runner can learn the ground being drilled. This knowledge is the testimony of core and sludge, and as furnish- ble in the hole. Many operators will not entrust ed machine to a runner who has not had 2 or 3 similar drill, nor give a man work on a deep hole ole experience with shallow ones. In general, runners for screw-feed machines. The helper is unner in handling the rods. Besides the above ually required, who may act as foreman for as for.

vs. A group of drills will require a general foreman. art or all the time, to haul fuel, attend to water supply, runner are usually slightly higher than miners' wages in usual helper's wages of the district. Bit setter is paid runner, minimum wages being $100 to $125 per month. ve lists of experienced runners and bit settlers available raveling and living expenses besides regular wages.

per day depends upon: size of drill and consequent ize of hole and rods; sp gr of the sludge; whether hether the hole leaks or is tight; and whether the of water in the hole is to cool the bit and raise the tter it will suffice for the former. If no water chan- ore barrel, the maximum size of particle that can pass qual to the clearance of the outside diamonds. With rmined by clearance between rods and sides of hole.

per sec is usually satisfactory. To maintain this requires hole, 100 gal in an *A* hole, 60 in a *B*, and 350 in an *N* hole,

using rods of the same letter (see Bits and Fittings, Art 10). With this rising the velocity in the restricted space around the core is considerably higher, re so great loss of core in soft rocks that quantity of water is usually reduced. I much water means rapid progress and low core recovery. Little water increase covery at the expense of progress, and too little water may result in a burned bi hole is tight and all the water pumped down returns to surface, the overflow fro box can be reused. Loss of water is then about 25%. In reusing, the water freed from oil, else the passages will clog.

Coal consumption ranges from 3.5 to 10 lb per working hr per rat hp, according to quality of coal and condition of boiler.

12. Time Distribution in Diamond Drilling

Time efficiency in drilling is the percentage of total working time i actual cutting of rock is done. It rarely exceeds 60%, and depends upo and character of overburden, time consumed in hoisting and lowering r time lost in delays. Time for handling rods depends on depth of hole, an between breaks. Number of lifts necessary depends on nature of grou of bit, and kind and length of core barrel. Uniform ground will so core the full length of the barrel. Cores in broken ground break up and barrel, or are lost. The double core barrel (Art 10) tends to overco difficulty. A solid bit need be raised only to change it.

Table 36. Time Distribution on 8 Shifts Diamond Drilling, Dome Mi Canada (15)

Aver hr per time for pulling and lowering rods are found by finding the aver hr p per 100 ft, and multiplying by the aver depth. These figures agree so closely wi individual times for the different depths that the arithmetical averages of drilli waste time can be legitimately taken.

Table 36 shows that, for holes from 550 to 820 ft deep, actual cutting time av but 64% of drilling time, raising occupied 16.2%, lowering 12.5%, incidental delays Table 37 shows for holes 236 to 568 ft deep: 37.7% cutting time, 27.9% handlin and 34.4% delays, some of which should probably be classed as extraordinary. (M tearing down and setting-up are excluded.) Table 38 shows for shallower holes: cutting time, 22.1% raising rods and 14.1% lowering, incidental delays being neg The higher percentage of time here consumed in handling rods is due to the short (10 ft). Obviously, in using these figures, weight must be given to the progress actually cutting and to the nature of the ground, since both factors affect the perc of time consumed in handling rods. But, figures cited are fairly representative of d

Delays due to character of ground, and current repairs and renewals on t
are incidental to all drilling operations. Allowance of 10 to 20% of the tim
mated for drilling (including handling rods) will generally cover incidental d

Table 41 gives delay record on 19 holes from 78 to 2 172 ft deep on the Rand, in
incidental delays ranged from 0 to 34% of drilling time in rock, with an aver inci
delay of 14.3%. Table 42 is an analysis of the delay record on 3 holes at a Mic
copper mine.

There are other delays, due to breakage of tools in the hole; loss of stones fro
bit; dropping objects down the hole; breakage of the rig; lack of fuel, water, or
necessary tool. These cannot be foreseen and must rank as extraordinary. Many
from poor management and careless running. Time allowance to cover these item
matter of individual judgment.

13. Diamonds, Bit-setting, and Loss of Carbons

Diamonds. Two varieties are used for drill bits: (*a*) Carbon, a n form of pure carbon, granular or compact in structure, without cleavage 3.1 to 3.3, black or grayish black in color. A fresh fracture has appear broken steel; some stones have a greenish or brownish tinge. Nearly al from Brazil. (*b*) Bort is imperfect, or flawed brilliant; occurring in rounded forms, with radiated or confused crystalline structure. Bot and carbon have a hardness of 10, but the crystalline structure of bort it more liable to breakage, and it is not suitable for hard rocks. Cubi roughly spherical carbons are best. Irregular, flat, and pointed forms a to set, and wear unduly on account of breakage of the projections. diamonds has fluctuated greatly in the last 35 years; general trend be ward (Table 43). Small, or poorly shaped stones can generally be pu

a. For special grade or extra choice stones the prices, particularly in latter y run $8.00 to $10.00 higher per carat. (Prices from Sullivan Mach'y Co.) *b*. corded in technical journals. Lowest are for carbons of inferior grade, poor small size. *c*. Price of bort is usually 20 to 25% of the price of first-class carbon

below market price, while the larger, well-shaped stones command a p Fragments of less than 0.25 carat are known as scrap; price in 191 $3 per carat, with carbons at $85 to $90 per carat. Selection carbons requires judgment and experience of an expert. Lacking judgment, an engineer should buy through a reliable dealer or diam manufacturer.

Bit setting requires skill and experience, and is an important op Diamonds must have such clearance that the metal of the bit will not contact with the rock, and be arranged to "cover" each other, so that of the area to be cut will fail to be touched by a diamond at each revol the bit. Number and size of stones used vary with size of bit.

The *E* and *A* bits (Art 10) are usually set with 8 stones totaling 12 to 16 cara 4 1-carat stones were used on an *E* bit at Miami, Ariz. Practice in the Lake

14. Recovery of Core

Core recovery is highest in hard uniform rocks, in which it may reac
It is lowest in loose, soft, cleavable and broken rocks, where, unless th
run almost dry, and rods are raised every few inches, recovery may not
to more than 10%. Vibration of rods causes low recovery. For good
in hard rock the drill should be run with low speed and heavy pressure;
rock, the reverse. Recovery is invariably less in upper than in lower po
holes, due to decomposed character of rock near surface.

Porcupine increased core recovery. Drill ed down until the core was packed in the ome typical rocks on the Rand. Table 51 g progressive decrease with size of bit. E.

Size of hole is determined by the depth to be bored, and purpose of hole. To obtain a core in soft, friable minerals, as coal and salt, the inside diam of bit should not be less than 2 in. For hard rock or ore, a 1 3/16-in to 1 1/4-in core is large enough. If the stratum or ore-body to be sampled lies deeply, the hole must be begun larger than this for larger and stronger rods, and to give room for casing without excessive reaming, should casing be necessary.

STANFORD LIBRARIES

15. Speed and Cost of Diamond Drilling

Speed is affected by: kind of rock and surface covering; depth, direction, a ation of hole; quantity of water in hole; kind of drill, fittings, and accessor core requirements; labor, climate, and continuity of work; percentage of

Speed of actual cutting is faster in soft rock than in hard. Rate of advance in uniform rock than in alternating hard and soft strata; it is low in shattered an rocks. Hard uniform rocks that core well drill faster than soft rocks which gri the core barrel. Caving decreases speed. A shallow surface covering will increase speed in the hole. Tables 48 to 54 give rates of advance in differe Table 48 shows a fairly consistent decrease in speed and increase in delays, with in percentage of surface covering. Bouldery surface covering decreases spee hole (Table 52). Rate of advance in rock is generally greatest in the second a hundred ft (Table 53). Decomposed top rock decreases speed for depths less ft, and the longer time spent in handling rods decreases it below 300 ft.

* Diorites, compact garnetites, & hard, silicious eruptives & limestones, classified by drillers as hard rock. All ores, greenstone, classified as medium. *a*. 8-hr shift underground. 9-hr shift on surface. Speed in flat holes about 15% greater than in steep. *b*. Contract work tried May 1906, but found unsatisfactory. No work June & July either year. *c*. Crew normally runner & helper, with additional labor on moving, water supply, teaming, etc. Drill runner at $175 per month set & was responsible for diamonds. Helpers, $3.50. *d*. Electric power (air from elec-driven compressors) is estimated on assumption that a diamond drill requires same quantity of air as a 3.25-in piston drill, or about 20 hp. *e*. Incl 15-mile move to another mine. *f*. Caving ground caused considerable lost time. *g*. Steam direct from 24-hp boiler; required engineer & team to haul wood. *h*. Incr in power cost due to partial closing of mine; hence, a greater propor of power-house expense was borne by the drills. *i*. Incl tools & miscel supplies. *j*. 1 9/16-in hole; 1 3/16-in core. Sullivan Beauty drill.

Holes 1 to 8 steam holes 9 to 16 hand-drilled. Steam crew: 1 white and 5 or 6 natives. Hand-dri 1 white and 8 natives. (*d*) Exclusive of moving time. (*e*) S, shale; SS, sands

Between the horizontal and vertical the inclination of the hole has little effect o In the same formation, holes pointing upward drill slower than those pointing do because of the awkwardness of arrangements at mouth of hole. Occurrence water in such a hole adds to inconvenience in drilling, and tends to retard prog

Whether the drill is working underground or on surface makes no appreciab ence in speed, once the drill is set up. Moving is usually more difficult undergro the moves are likely to be shorter and several holes are often drilled from on Holes drilled from scows into subaqueous strata always advance more slowly than similar formations where the drill can be set up firmly. Rate of advance per d increases with size of drill. But, rate per working hr may be greater with a ligh heavy drill, when holes are shallow and moves frequent (Table 54).

In rock which cores well, the longer the core barrel used the faster the adva soft friable rocks, if high core recovery is essential, use of double core barrel will speed. Taking cores 2 in and smaller, size of core has no appreciable effect o provided drill is not working beyond its rated capacity. Larger holes will dr slowly. Holes drilled with a solid bit advance faster than those with an ann unless the hole is of large diam. Best quality of carbons, well set, gives fastest p

An experienced and skilled runner is essential to rapid progress. Character c labor also has considerable influence on the speed. Holes drilled by contract show higher speeds than those on company account, unless great difficulties and contractor can not finance added expense. Bonus system is sometimes ful. The danger in contract and bonus systems is that unless a minimum perce core recovery is stipulated increased speed may be gained at expense of core r Unfavorable climate, cold or tropical, retards drilling. Drilling 24 hr per day gives a greater speed per working hr than one-shift work. In the latter, time is in starting up, and usually also at end of shift, due to fact that it is unsafe to le drill with the rods in the ground.

r working hr; prices of supplies, fuel, power consumption; and accessibility o.) ies to the shot drill, with exception of:
re, method of collecting sludge, and feed

STANFORD LIBRARIES

mechanism. The bit (Fig 54) is a steel cylinder, with a diagonal slot in lower edge. It is screwed to the core-barrel *A* (Fig 55). Chilled shot are fed through the rods, and pass between core and inner wall of bit to the bottom of the hole where they cut by a milling action.

Fig 54. Bit for Shot Boring

The bit slot allows much of the drilling water to rise without tending to lift out the shot by passing under edge of the bit. It also allows slot which have worked up the walls of the bit to fall back to the bottom. An annular toothed bit, recommended by the makers, for soft rock, has had little success. Most shot drills dispense with a mechanical core lifter; the core is gripped by wedging it into the core barrel with angular pieces of quartz, called grout, dropped down the rods. The sludge collector, or "Calyx," is a hollow cylinder, open at top, and of same outside diam as the core barrel. The rising current passing above upper edge of *C* loses velocity in the larger cross section, and deposits the coarser sludge in the cylinder. To carry this material to the surface would require a high quantity of water. The rods are screwed to lower end of drive rod, which is rotated by bevel gears and a spline, as in the diamond drill, or square drive-rod. On upper end drive rod is a water swivel, to which is attached a yoke. From the yoke depend 2 reins, put in tension by a hand-operated winch or lever attached to the engine frame. After first few hundred ft, the weight of rods gives sufficient pressure; hence the feed mechanism is simple.

Table 61. Sizes and Weights of Shot-drilling Tools
(Ingersoll-Rand Co)

Size of tools, in.....	2.5	3.0	3.5	4.5	5.5	6.5	7.5	8.5
Hole diam, in.....	2.75	3.25	3.75	4.75	5.875	6.875	7.875	8.875
Core diam, in.....	1.5	2.0	2.5	3.375	4.5	5.5	6.375	7.375

Limitations, as compared with diamond drill, are 3 in number: (*a*) In soft rock the shot become imbedded, stopping the milling action; (*b*) Angle at which the drill can bore is from about 45° to vertically downward. With greater deviation the shot collect on lower side of hole, and bit cuts unevenly or ceases to cut at all. Maximum angle of deviation is less with bits of small diam than with large; (*c*) About 4 in is the minimum economic bit diam.

Other limitations, as loss of shot in creviced ground and inability to drill hard rock, have been alleged, but F. W. Sansom attests to its ability to drill the creviced limestones of Joplin district, Mo, and Ingersoll-Rand Co report 16 in advance in 56 min actual drilling time in corundum-bearing rock; 3.25-in hole, 2.375-in core, with consumption of 3.82 lb of shot and 0.32 in of bit.

Combination churn and core-drill rigs have been evolved to meet the first limitation above mentioned. Fig 56 shows a portable rig of this type. *a* is the core-drilling mechanism, *b* pump, *c* hoist or bull-wheel, *d* engine, and *e* the spudding device. A collapsible derrick is mounted on the frame. With this rig a hole can be quickly churned through soft formation that defy the core drill. Another advantage of the combination rig is that a churn drill will bore more quickly to a known horizon, after which the shot drill can be used to take a core.

With obvious changes, the list given for diamond-drill outfits may be used for the shot drill. Table 62 gives approximate weights of outfits, including equipment [illegible] necessary near supply. For remote districts, add about $100 to the $500 to $1,000 for the larger drills, in addition to the 300-ft [illegible] allowed in estimate for steam rigs, [illegible] motors with

boreholes. Hoffman (29) describes
lecting 2 boreholes; one in order to take
he vein through same hole, the other to
when 3 previous attempts had failed on
essive deviation. Apparatus used in the
ary mines' Vlakfontein borehole (Trans-
l of a pilot wedge, guide wedge, and main
lge. Mode of procedure was as follows:

in diam, the pilot wedge (Fig 76) was made
on, 18 in long, with a 6-in wedge face. The
e wedge face was threaded to fit a piece of
0.75-in hole was drilled in face of wedge and
k *a*, for surveying purposes, was made with
of wedge. The wedge was then screwed into
5-in pipe, jagged at the opposite end (Fig 77).
was filled with water and the pilot wedge and
together, were dropped in with wedge face up.
were then lowered to find out whether the
l pipe were resting on bottom of hole. If not,
aised by means of the tapped hole and dropped
ested on solid bottom, or was wedged tightly
n. Position of the wedge was then surveyed
on an oriented lead block. The guide wedge
wedge, without the tapped hole in beveled end.

STANFORD LIBRARIES

The butt end of guide wedge was screwed into bottom of main deflecting wedge (Main deflecting wedge was made of a 7-ft piece of 2-in round steel, the bottom en drilled and tapped to receive the guide wedge, and the other end was drilled with a bit for 2 in, leaving a ring of metal ⅛ in thick. The solid portion of the 7-ft len then planed, beginning at the under side of the metal ring, down to about 1 ft from forming a wedge with a 1-in radius concave face, a thickness of ⅛ in at top and bottom. The direction of face of pilot wedge was known from the survey, so t guide wedge was screwed up to turn the main deflecting wedge in the desired di when faces of pilot and guide wedges were in contact. One end of a 1⅝-in rod wa in the metal ring at top of main deflecting wedge, and riveted to it with 2 0.25-in rivets; to the other end of the rod was attached 10 ft of 1⅜-in rod, connected to t line of rods by a ball-bearing swivel. On lowering the apparatus into the hole, th wedge engaged the pilot wedge, and turned main deflecting wedge into the prop tion; pressure was applied to shear the copper rivets, and the rods were raised, the deflecting wedge in the hole. When the position of the wedge was found cor survey, drilling was resumed with 1⅝-in tools, the deflecting wedge acting as a g throw the tools into a new line.

In the Witpoort (Transvaal) borehole a means was devised to overcome neces reducing the diam of hole at each successive deflection. After the main deflecting was set, the 1.625-in hole was drilled about 12 ft deeper and the wedges were withdr a recovery tap. A 13-ft piece of 1-in round iron, bent about 0.25-in out of lin fastened to the end of the rods by 2 copper rivets, lowered into the hole and manip until it passed into the branch hole. The rivets were then sheared, the piece left in and the hole cemented to about 1 ft above top of the iron. After the cement ha drilling was resumed with 2.125-in bit. The iron in the hole passed up into the h it over into the branch, and was brought up in the core.

18. Choice of Boring Methods

Chief factors: (*a*) depth of hole; (*b*) speed desired; (*c*) first cost of (*d*) operating cost; (*e*) character of material to be penetrated; (*f*) tra tation facilities; (*g*) information desired.

For shallow work in earthy material or soft rock, a hand rig is ordinarily pref For holes more than 50 ft deep, or in hard rock, a power rig should be used, unless inc first cost, including transportation, outweighs the saving. Speed increases, in ge with size and weight of rig, except that for shallow holes and frequent moves the g time consumed in dismantling, moving and setting-up may offset the greater d speed. Core drills cost more than churn or hydraulic rotary drills; and first cost mond drills, including carbons, exceeds that of shot drills. Churn and rotary d are usually cheaper than core drilling, but the question of operating cost is so close lated to the purpose of the work, character of material penetrated, and labor avai that each case should be considered separately. Character of the material is some the determining factor. Thus, the hydraulic rotary is preëminently suited to d in the soft ground encountered in oil wells in the Gulf-coastal plain, other types o failing completely. Diamond drill is unsuited to very soft or badly shattered hard To secure information as to physical character of or for rock in place, core drill must be

PROSPECTING AND EXPLORATION

2. Conditions Warranting Prospecting

Search for mineral is largely guided by knowledge of the geological ass tions and peculiarities of known orebodies. It is done chiefly by miners who absorbed the details of ore occurrence in mines where they have worked. are keen observers, but prospect only for types of orebody covered by experience. This results in many discoveries by inexperienced men who pect without preconceived ideas. Some famous orebodies have been fo accidentally. Crane (2) lists 130 gold and silver mines in the U S, of whic were discovered by chance.

Theoretically, the trained economic geologist should make the best prospector, bu chance of finding commercial orebodies is so small that such men can not afford to pro unless employed by mining corporations; under present conditions, scientific prospec is rare. Engineers generally direct the work of exploration. Economic geology aid

old workings. Very narrow veins are indicated by narrow workings, with sm containing much waste. (*e*) Grade of pay shoots, vague, but above aver grade if high values be rejected. (*f*) Large and abundant dumps in comparison wi workings, especially dumps containing large pieces, indicate low-grade ore sparse dumps along strong workings indicate that whole vein was worked as pay that its grade was probably good. Roughly, the value of a vein is proportion ratio between extent of old workings and extent of the dumps. (*g*) No light is t old workings on permanence of the vein in depth or on its gold values.

3. Prospecting Methods

Surface methods in common use are: tracing float, tracing by p trenching, and test-pitting. Search for mineral which does not outcrop at considerable depth is done by boring (Art 8), or shaft sinking (Art Sec 7). Methods are varied and combined to suit local conditions or th of the prospector. There are many prospecting devices for use in specia

Tracing float (Cornish, "shoading"). Pieces of ore (float) are brok outcrops by processes of erosion, and gradually work their way downh streams, where they may be carried long distances. The prospector float on a hillside, or in a gulch or stream, tries to follow it back to its sou rough idea of the distance which float has traveled is gained from the s abundance of pieces, and their roughness or water-worn condition.

Many outcrops which are the source of float are concealed by a covering of such cases, at some point below the outcrop the float disappears, or "goes Trenches or test pits are used to follow float farther. The distance between soil- outcrops and the point at which float goes down varies with depth of cover, topo and climate. On flat slopes (6%) in desert regions of southwest U S, float has bee on the surface within a few feet of outcrops covered with 1 to 2 ft of soil. In Ma district, Mont, at one point float went down on a hillside and was followed by pits ft before finding the outcrop; bedrock was 10 ft to 12 ft below surface. In the fa where freezing and thawing have gone on a long time, the "creep" on the hillsides and float may be found far from the outcrop.

In general, tracing float is applicable only in searching for ores tough enough to disintegration by erosion. Gold-quartz, or pyritic ores with siliceous gangue, in p lar, yield float which is resistant and easily recognized. The value of, and result the method depend largely on the personal equation of the prospector. Knowl ore, keen observation, physical strength, and unending patience are essentials. prospectors use the pan or horn spoon to estimate the content and value of float, because of expense and inconvenience of obtaining assays.

Tracing by panning (also called "tracing" in western U S, and "loam in Australia). This, like tracing float, is based on recognition of the resi erosion. Weathering releases small pieces of metal and minerals from out and these migrate downhill as do pieces of float.

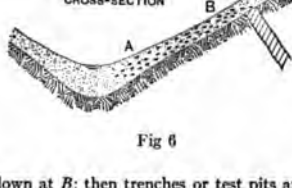

Fig 6

Fig 6 shows an orebody outcropping a soil cover, and the usual position o metal or sulphides derived from it by e In a new district, the prospector along the bottom of hillsides at an ele (*A*) sufficient to avoid the debris brough the gulch from upstream points. Sa of the top 2 or 3 in of soil are panne specks of metal or sulphides are found, ning is continued uphill until the trac down at *B*; then trenches or test pits are dug. The placer miner's pan, or a fryin 4 to 6 in diam, is used for panning. In practiced hands the latter gives accurate re and is better where scanty. Float found in connection with this work sho crushed and panned as an aid in determining the source of "traces." This metho developed by "pocket hunters," and has been used chiefly in prospecting for gold, w

Cross-section of test pits may be circular, elliptical, or rectangular. **Diam o** pits is 30 to 36 in; elliptical pits are 36 to 42 in long by about 28 in wide; **rectang** are rarely smaller than 4 by 4 ft or 4 by 5 ft. In point of cost and speed, **small** pits are preferable to rectangular; the amount of material to be excavated **and** from a 36-in circular pit is about 0.35 of that from a 4 by 5-ft rectangular **pit.** or elliptical pits are excavated with a short-handled pick and shovel; **the** straddles the handle. A windlass is used for hoisting. Galvanized-iron **water p** good buckets for small pits; ordinary windlass buckets are better for **larger rec** pits, 2 buckets or pails being provided for each windlass. A 0.25-in wire rope s used instead of a hemp rope in small pits over 30 ft deep; at greater depths, the t hemp rope across the windlass barrel is apt to throw the bucket against the walls lodge loose material. Objections to circular or elliptical pits: (*a*) they requi trained and willing to work in an awkward position; (*b*) there is no room for dri blasting, if boulders are encountered; (*c*) it is practically impossible to timber th rectangular pits a soft stratum can be close cribbed with plank at slight expen crew on either kind of pit consists of 2 men, one digging and the other on the

Cost. Prospecting for brown hematite in Georgia and Alabama. **Round tes** to 36 in diam; depth, to 50 ft; cost, 35 to 50¢ per ft. In ordinary unconsolidated 2 men sink 10 ft per day (5). Near Birmingham, Ala, a large number of 30-in pi 60 ft deep, have been sunk at 35 to 45¢ per ft; speed of sinking, 18 to 20 ft boulders of ore and rock frequently reduce speed to only 8 ft per day (6). Ecl that, for iron-ore prospecting in U S, the cost for small untimbered test pits, 10 deep, is 30 to 50¢ per ft (7). In Lehigh Valley, Penn, 2 men sink 30 to 36-in pits t of 50 ft at 20 to 30 ft per day (8). In Nevada, the author sank 40 by 29-in ellipti with Chinese labor, in easy gravel, at 20 ft per 12-hr day for first 40 ft. Below 40 f was hard and clayey. Aver speed for depth of 100 ft was about 5 ft per 12-hr sh tract work). Under same conditions, white labor on day's pay averaged 2 to 3 ft p shift in test pits of 4 by 5 ft cross-sec.

E. S. Dickinson gives following data, referring to Table 1: cross-sec of pits, 4 the ground dulled picks rapidly; foreman's wages, $3; laborers, $2. Pits cribb 2-in hardwood plank; cribbing removed and reused. Work done by 3 men; each in a separate pit as long as he could throw dirt out, then another man helped by t dirt back from edge of pit. Pit was deepened by help of a platform, one man sh from bottom, the other shoveling from platform to surface. When depth beca great to allow this, or sooner if many boulders were encountered, a windlass was i and 3 men worked together on one pit. Cost of superintendence is not included i

Table 1. Costs of Test Pits in Clayey Hardpan, Many Large Boulders

Pit	Depth, ft	Hours labor	Total cost	Cost per ft	Pit	Depth, ft	Hours labor	Total cost	
1	17	80	$18.00	$1.06	9	38	255	$64.00	$
2	24	140	29.00	1.21	10	33	240	54.00	
3	7	15	3.50	0.50	11	10	60	12.00	
4	22	75	16.50	0.75	12	9	100	22.00	
5	23	100	24.00	1.04	13	9	20	4.00	
6	26	240	48.00	1.84	14	17	60	12.00	
7	41	270	56.00	1.37	15	12	55	12.50	
8	46	335	72.50	1.58	Totals	334	2 045	$448.00	$1

Aver depth, 22.3 ft; aver speed per hr, 0.114 ft.

The author sank 11 rectangular test pits; aver cross-sec, 4.1 by 4.7 ft; aver 7.5 ft; material, very hard clayey gravel overlaid by 6 in loam; deepest pit, 10 windlasses used; labor, 161 man-hr; aver speed, 0.51 ft per hr. In Lake Superio districts, rectangular test pits cost about $1.25 per ft. For other details see Art 7 Sec 3, Art 11. For use of test pits in systematic surface exploration, see Art 6.

force existing between portions of an orebody. Extensive experiments at Virgi and Eureka, Nev, showed that differences in potential are very minute and so err they are useless as a basis for prospecting (15).

Electroscope. Radio-active minerals have the power of discharging troscope; under suitable conditions the rate of discharge is proporti amount of radio-active substance in the mineral. Electroscope is engineers and prospectors to detect radio-activity, and for quantitativ Radium is obtained solely from uranium ores, the amount of radium b constant relation to amount of uranium present; normally 1 unit of ura accompanied by 3.3×10^{-7} units of radium. Thorium compounds and also discharge an electroscope.

Fig 8 shows a simple electroscope suggested by B. B. Boltwood, which can be the field. It consists of a 5-cent piece, a quarter dollar, or an iron washer A; sealing wax or candle grease C; an upright B made fro of tin 0.2 in wide (or a 6d or 8d wire nail flattened at the leaf D. The latter may be a piece of aluminum le 0.1 in wide, obtainable from any dealer in painters su thin tissue paper, both sides of which have been coa graphite by rubbing with a soft pencil. Leaf is attach right with mucilage or flour paste. Bottom of upright be insulated from base A by a layer of sealing wax; must not be touched with the fingers after it is in p cover protects the apparatus from air currents; for th sions shown in Fig 8 an ordinary glass tumbler placed upward will serve. Electroscope is charged by touchin right with a piece of hard rubber (a fountain pen), o wax, which has been electrified by rubbing on one's sleeve. A protractor drawn on cardboard, so that i point is at same height above base A as the point E, is placed behind the tumbler angle read between leaf and upright. Readings are repeated at regular interva termine rate at which electroscope will discharge itself by leakage. The mine tested is placed inside the tumbler; radio-activity is proved by a rate of discha than that due to natural loss of charge.

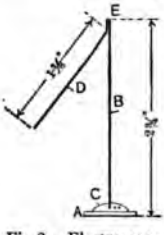

Fig 8. Electroscope

This crude electroscope gives surprisingly accurate quantitative results if hand fully. Table 2 shows results of tests by H. G. Mead under author's direction, o of samples prepared by mixing pitchblende (35.7% U) with inert material in pr portions to give samples containing 2, 5, 10, 15, and 25% U. Samples were through 20 mesh and placed next to base of electroscope in a small pill box. Sa box was used for all samples, each being filled level full, and placed in same posit respect to electroscope. Rate of discharge was determined as above, corrected fo leakage, and net rate of discharge computed in degrees per min per % U. Max e paper and aluminum leaves were 0.7% and 1.9% U respectively. Aluminum leaf more sensitive than paper, and requires greater skill and patience in mani

conditions in a 40-acre tract. Observations are first taken along boundaries a intervals (say 100 paces); max dips occur at *A* and *B*; stakes are set on line *AB* vals of 100 or 200 ft and readings taken on lines at right angles, as on *DE*. Re platted and a line drawn connecting points of max dip, which lies approx over t netic slates. Lines at right angles to *AB* are then staked out 300 ft apart, and exp is conducted by boreholes at regular intervals along them (see Art 11).

Results of dip-compass surveys are usually platted to scale and is LINES (connecting points of equal dip) give information as to form and of underlying orebody. Following are general rules for interpreting such Isoclinic lines are normal to lines of force in the magnetic field produce orebody, and they are adapted to indicating mild but extensive fields dips occur over the magnetic pole of orebody or the enclosing areas around the outcrop. Small orebodies near surface may exert as much at as large orebodies deeply buried, but their effect extends over a small Slow steady increase of dip over a large area indicates a large deposit; dip limited to a small area indicates a small deposit. Lean ore near surfa give same indications as rich ore in depth.

Horizontal-compass surveys. Observations are made at regular i over the area to be tested, by same general methods used with dip c The needle is used to measure local attraction caused by magnetic or A preliminary transit survey may be made and lines established by m which compass is oriented. For rapid and extensive work the dial con preferable; "it consists of a small portable sun-dial, provided with a c needle swinging within a graduated circle, which, when instrument is horiz. On a sunny day if instrument is set up, leveled and turned in until shadow of the gnomon (a thread) falls on the division of hour-circl sponding to apparent time, zeros of graduated circle are in true merid needle gives declination" (117).

For correct results, hour-circle must be graduated for a latitude near point of tion, angle between gnomon and plane of hour-circle must = latitude, zeros of circle must be in vertical plane of gnomon, plane of hour-circle must be level, parent time must be known. Apparent time is obtained from standard time by c for difference in longitude between point of observation and standard meridian, addition or subtraction of equation of time obtained from a solar ephemeris (Sec 13). W. L. Cumings gives following method of determining solar time (117). free from local attraction is selected, dial-compass is used to make an observ Polaris, and a suspended string is lined in between star and compass sights. Aft ian is determined, compass is set on it while sun is shining and the threads' shad true solar time. Observer's watch is set to this time, and used for orienting co subsequent work; compass is set on meridian each morning for correcting watc

Platting. Compass deflections are platted to scale on a map and is LINES (Sec 17, Art 10) drawn connecting points of equal deflection, inter where necessary; surface contours should also be shown.

Interpretation of maps. H. L. Smyth gives following points: Final assumed by needle influenced by a magnetic orebody is in a line which is sultant of the horiz component of force of the earth's magnetism and tha deposit. Important points to be located are those of zero and max de called CRITICAL POINTS. Relation of critical points to deflections of nee their position with regard to disturbing forces, are illustrated by consid of several partly ideal cases:

(*a*) A single magnetic pole, regarded as upper (north) pole of a vertical-bar lying at a depth *h* below a level surface, the lower (south) pole of which is too far affect compass. In this case, angle of deflection is a function of 2 variables, the of point of observation from the pole and its direction from pole. Point of zero is directly over pole; points of max deflection lie on a circle the center of whi

ervations. Under assumed conditions, $h =$
ntric circles, the center of which is over pole.

the value of R is found from expression, $R = H\ (\sin A_0 + \sin A)$. Results are plot scale, and R and H drawn in at each station. F is then found graphically by comp the parallelogram of forces at each station; lines F will converge towards magnetic of deposit C and indicate its position.

5. Geological Data for Prospecting and Exploration

(By J. D. IRVING, Professor of Economic Geology, and A. M. BATEMAN, Assist Professor of Economic Geology, Sheffield Scientific School, Yale University)

a. Introductory

All mine exploration rests upon some geological theory as to the probable position, size, extension, mineral character, or value of an ore mass. Correct geological kno frequently enables one or more of the above features to be determined in advance ploration, often with considerable accuracy. In some cases geology furnishes n whatever, and exploration is necessarily blind. Following are some common con under which geology may aid in exploratory work, with methods by which results n secured. (See also Sec 2, Mineral Deposits.)

Sources of information: (*a*) PROCESSES OF ORIGIN OF A DEPOSIT dete its form, size, and geological position, the mineralogy and value of the pr ore, probable occurrence in undeveloped districts, and success or failure ploration for more ore in a partly developed district. Production of ore r is only one of many effects of ore-building processes. If the other effects recognized, they may assist in discovering ores. Favorable indications insure ore occurrence, but, if they are entirely lacking, ores of the type no cated will almost certainly not be found. (*b*) PROCESSES OF SUPERFICIAL AL TION acting on an orebody after its formation. These determine infe from nature of outcrop as to value of undeveloped orebodies, depth to developed ores may be expected to go, and often the presence or absence

Table 3. Classification of Ore-forming Processes

Ore Deposit Group	Process of Deposition
I. Bedrock (or primary) deposits	Due to processes operating on bedr
A. Syngenetic deposits	Due to rock-making processes
1. Igneous	Due to magmatic differentiation proces
2. Sedimentary	Due to processes of sedimentation
B. Epigenetic deposits	Due to processes of mineralization
3. Fillings of cavities	Due to chemical deposition in rock ope
a. Fissure veins	
b. Other rock openings	
4. Replacement deposits	Due to processes of metasomatic replac
5. Contact metamorphic deposits	Due to combined processes of contact amorphism and replacement
II. Disintegration (or secondary) deposits	Due to processes of disintegration a concentration at the surface
6. Mechanical concentrations, placers	Due to sorting action of water or wind
7. Chemical concentrations	Due to chemical deposition at surface
8. Residual concentrations	Due to removal of worthless matrix
III. Metamorphic derivatives	Due to process of dynamic and r metamorphism acting on pre- deposits of all kinds or on roc

This grouping is not intended to supersede other classifications, but to show the of processes of ore formation to the genetic classification on which the practical c ations that follow are based.

orebody at all. (*c*) TIME OF FORMATION OF A DEPOSIT, relative to other g events, determines the time relation between undeveloped ore masses and intrusive rocks, metamorphism, sediments, and all geologic events whic

rossularite garnet, epidote, and chlorite
alteration or metamorphism). They are
ich they are a part or the whole, are never

STANFORD LIBRARIES

surrounded by a halo or zone of sericitic or propylitic alteration, which dec as distance from the deposit is gained, and they constitute a small group c each associated with its own rock type. They are distinguished from c metamorphic ore masses by absence of contact metamorphic gangue mi from replacement deposits by absence of non-igneous gangue minerals a dences of intense hydrothermal alteration common with replacement type

Practical applications. Marginal igneous bodies result from different they are usually of irregular form, and only those of large horiz dimensic likely to extend far below the surface. This is more true for masses nearly dimensional in plan than for narrow and roughly tabular masses along the of the parent mass.

Extensions in depth are unlikely to exceed surface dimensions, though exceptio occur. Tonnage possibilities can not safely be predicated on surface showin igneous deposits there is commonly no abrupt wall between ore and parent rock; merge gradually into each other; hence, exploratory workings in the transitional p can not be expected to succeed. Underground exploration for ore masses not reve outcrop are unlikely to be successful; surface exposures are apt to equal or exc size and number of masses found in depth. Exploration should follow the cont tween igneous mass and country rock. In all bodies of igneous ore, primary mine curring near the surface persist to any depth to which the deposit may go, except for c produced by superficial alteration. Any change in tenor with depth is accidenta

Search for orebodies in undeveloped districts. Igneous orebodi not accompanied by extensive mineralization (sericitization, propylitizatio of the country rocks; for example, the granite rocks outside of the Su nickel ore masses are fresh and unmineralized. The prospector has but o dication of probable or possible presence of an orebody of igneous origin; t the existence of a body of igneous rock of the kind usually associated with ticular kind of ore. Such associations are valuable guides; *per contra*, absence throws suspicion on any reputed occurrence. Search for diamon Arkansas was initiated by discovery of the correct type of rock. Co associations are:

Nature of deposit	Parent igneous rock
Diamond	Peridotite
Nickeliferous sulphides	Hypersthene-gabbro or norite
Non-titaniferous magnetite	Syenite, syenite-porphyry
Titaniferous magnetite	Gabbro, norite, peridotite
Chromite	Peridotite (& its metamorphic derivative, serpen
Corundum	Peridotite, nepheline syenite

The rock mass being discovered, search should be made along its conta orebodies (except in case of diamonds, which are scattered through the entire r

Peripheral igneous orebodies bear a definite relation in size to the parent igneous since large orebodies can not be concentrated from small bodies of rock. If size of i igneous body can be determined (allowance being made for small exposures repres large subjacent masses), it affords a clue to size of possible ore masses. Sulphide ig orebodies sometimes concentrate at points where the igneous body makes an ou embayment; hence, such places should be prospected.

Central concentrations are rare and occur only in certain very basic rocks, b possible existence should be recognized.

Syngenetic igneous orebodies occurring as dikes differ in no respect from igneous rocks, except that one or more of the constituent minerals may be of com value. There are no geologic features which will enable one to predict the occurr igneous dikes in a district. This is true also of dikes of ore; they are where you find Dikes are the upward offshoots of igneous bodies, and must lead to the latter. Th way in which a dike of ore (as at Kirunavaara) can terminate is by eventual tra

, though rare, are particularly reliable bodies

l igneous minerals; if non-igneous minerals Included angular fragments of country rock fused with horses in veins, since they are not ned from solution.

limentary Deposits

rs, are formed by sedimentation processes; presentatives in the U S. Such deposits are nerals of which happen to be of commercial cable.

dimentary layers may be confused with re- d by deposition in an opening made by the for distinction: (*a*) sedimentary layers are eplaced beds are local and found only where ntary orebeds have a narrow vertical range have relatively wide vertical range, but re- beds, in their occurrence, are independent ssociated with intrusive rocks. (*d*) In sedi- extensive with the sedimentary layer; with n the layer. (*e*) Beds adjacent to sedimen- replaced beds are usually highly altered by r other criteria see Replacement Deposits, ns is the fact that they usually jump across djoining rocks.

tary ore layers are the most uniform and ne origin being recognized, their extent over a geographic range (subject only to ne area of any given property. Thick- over the entire area, provided estimates d reach of surface alteration.

: Deposits

stricts containing epigenetic orebodies, equently that their associations with ore ital; their recognition aids materially in nce in any given region. They are: (*a*) s commonly, extrusive) rocks; (*b*) com- ; (*c*) extensive hydrothermal alteration lly increase in intensity as the mineral

STANFORD LIBRARIES

Mineralization. Ore deposits formed by circulating mineral solution accompanied by widespread alteration of country rock. But, deposition c and gangue is not the only expression of the action of mineralizing solu Examples of notable effects of some common types of alteration are as follc

Contact metamorphic alteration. Mineralizing solutions near contact metamc deposits produce contact minerals, decolorization of red rocks, and recrystallizati limestones, either as marble or lime silicates (see Contact metamorphic minerals, b Contact effects often extend to great distances from actual contacts. Other ty alteration may be superposed on them.

Sericitic and propylitic alteration of igneous rocks. Igneous rocks, poor in silicates, subjected to action of mineralizing solutions, change into an aggregate o flakes of mica, called sericite, often showing a little secondary quartz, and sometimes c which can be detected by feeble effervescence with acids. Sericite at times may b taken for white clay; it gives to the rock a dense white to grayish silky appearance; process has been extensive, the rock is usually soft and crumbles on exposure to air. citization is common in lighter colored igneous rocks; if intense, the rock often cor disseminated pyrite, which on weathering yields stained outcrops. Sulphates form surface alteration of pyrite change sericite into kaolin, the rock losing its silky lust

The first effect of mineralizing solutions on the darker, more basic igneous rocks change the darker ferromagnesian silicates (as hornblende and pyroxene) to a gre chlorite and to destroy sharpness of the component minerals. This is called prop alteration; further alteration results in sericitization.

Localization of ore deposits. In nearly all important mining distric the U S, ore deposits constitute a very small geographic unit, in the heart region of intense mineralization extending over a territory usually greate many miles than the area within which the ores occur.

Leadville, the Comstock Lode, Bingham, Park City, Coeur d'Alene, Butte, Cr Creek, Ely, Chino, Miami, Globe, Clifton, Cananea, and many others, are regions c tense mineralization, which extends beyond the limits of ore deposition. Hence, favo conditions for occurrence in a given locality may often be justly inferred from exte alteration. Where mineralization is slight, or confined to the immediate neighborhoc individual deposits, and has an inappreciable geologic range, orebodies are unlikely t large or numerous. There are few exceptions to this rule. The practical value of t phenomena is illustrated by the fact that the old-fashioned prospector, with years of p tical experience, always recognized them, though unconsciously. Deposits like th and Zn ores of the Mississippi Valley are exceptions. They occur in a region wit intrusive igneous rocks, structural deformation, or heavy thermal alteration. Possib of such occurrences in regions of undisturbed limestones should be borne in mind.

e. Fissure Veins

Types. (a) Simple cracks filled by deposition of mineral from solution; sheeted zones, consisting of parallel cracks, similarly filled with ore. In b types additional ore may be formed either by replacement of the walls or of included plates of country rock, with all intermediate gradations. The ore sulting from replacement of the walls may constitute the bulk of a depo Possibilities of large orebodies are greater in replacement veins than in th formed by simple cavity filling; hence, the prompt recognition of this char teristic is desirable. Fissures are almost always surfaces of complex curvatu The strike is never a straight line for any length; it changes sometimes by ger curves, sometimes abruptly.

Practical considerations. Prospecting, development, and exploration are often ba on assumption that fissures continue considerable distances along the strike observed one point. This leads to errors in locating crosscuts, shafts, or adits to intersect the ve and in locating claims with respect to the vein apex. Knowing the average strike duces risk in predicting extensions from a single exposure, but trenching should alw precede selection of sites for openings. Aver strike may be calculated from seve exposed points (Art 6). Reliable information can also be secured from aver trend of ol

are observable; this is particularly true of elow). For deflection of outcrops by topo-

ir size or continuity.

ns shows that most of them dip at relatively the North Star vein, Grass Valley, Cal (dip, d, that veins of low dip are never wide, be- close up the opening. Dip of a vein may t isolated points are unsafe, unless they are nembers of the same fissure system.

h. Alteration and Secondary Enrichment

Superficial alteration of ore deposits. Ex cold, recently glaciated regions, ore deposits at the surface undergo changes by superficial a which enrich their upper portions, or impoveri upper portions and enrich the lower. The proces SUPERFICIAL ALTERATION and SECONDARY ENRICH both performed by cold, descending waters, ca matter in solution derived from oxidation of the part of the deposit. Outcrops must be interpre the light of these changes; if the ore in shallow s workings is primary, no abrupt change may be exp for primary ores are subject in depth only to fluctu characteristic of their original formation. Seco ore may lead in depth to unworkable primary material, as at Ray, Ariz rich primary ores, as at Bisbee, Ariz. A knowledge of superficial chan criteria for recognition of secondary ores, and of the probable characteris orebodies below oxidized and enriched zones, is an invaluable aid in prospe exploration and development.

Alteration and enrichment processes. When surface water cont CO_2, O, etc, acts on an ore deposit, certain minerals are oxidized and with form solvents which dissolve metals (as Ag, Au and Cu), forming dilute sol which trickle downward. On reaching a point where O is no longer ava as at the ground-water level, their metallic content is, in favorable circumst deposited as secondary sulphide. The metals dissolved may be added to below, thereby producing secondary enrichment. As erosion progresse process is repeated; and both primary and secondary sulphides are diss and reprecipitated. A very considerable enrichment may result. In the mine, Ariz, the unenriched material contains about 0.25% Cu, the enri about 2%. The metallic contents of descending solutions may be depo before reaching the point where O is no longer available; in this case, seco oxidized ores are formed. The part of the deposit in which oxidation and tion goes on is the OXIDIZED ZONE; that where secondary sulphides are depo the SECONDARY SULPHIDE OR SULPHIDE ENRICHMENT ZONE; the unchanged of the deposit below, the PRIMARY ZONE.

e to redeposition from solution, or to
soluble minerals into solution and
deposit contains 0.1 oz Au per ton, and

STANFORD LIBRARIES

half of the ton is removed by solutions which do not dissolve the Au, the ore then contains 0.2 oz Au per ton.

Precipitation of minerals in oxidized zone may take place by; (*a*) Satur evaporation, by which most efflorescences are formed, as chalcanthite, goslarite portant deposits of brochantite. (*b*) Oxidation and hydration. The oxidatio gives rise to deposits of $PbSO_4$, which, being insoluble, remains in the oxidi in certain circumstances, $PbSO_4$ is transformed into $PbCO_3$. Similarly, forms deposits of limonite from iron sulphides; CuO and native Cu from erals; Ag and Au may be released from sulphides and left or precipitated in (*c*) Chloridization of Ag minerals in a deposit has formed important orebodies (*d*) Reaction with wall rock. Some of the metals in sulphate solutions may b tated by contact with limestone or other carbonates; for example, the carbonate ores of Bisbee and Leadville. If the solutions come in contact with SiO_2, metal deposited as silicates; for example, the copper silicates at Globe, Ariz.

Depth of oxidation may vary from a few inches to over 2 000 ft. depends on many variables, a few generalized rules may be of value.

In warm, humid countries of low relief and high water-level, a shallow oxid may be expected. In similar regions of high relief and low water-level, a deep zone may be expected. In widely glaciated regions, or where subjected to glaciation, the oxidized zone will be lacking or only a few feet in depth. In cold it is apt to be shallow; if oxidation took place in pre-glacial time, and the regio been extensively glaciated, the zone of oxidation may be deep, as at Kennecott where it attains a depth of 1 200 ft. In arid regions, with high water-level, it is shallow. In arid regions, with low water-level, it will probably be deep. In ari with no water-level, it may be deep or shallow, dependent upon how quickly the O was used up by oxidation in upper part of the deposit.

General inferences from oxidized zones. Most ore deposits have idized zone; it may be barren capping, or may contain oxidized ores; if the certain inferences may be drawn as to the possibility of ore beneath. If zone contains ores, these probably have been formed by superficial chan a change not only in metallic content, but also in metallurgical char to be expected below. This change is of vital importance in the pro life of the mine, and in the mode of ore treatment.

Precipitation as secondary sulphides. Sulphate solutions which lose their metallic content in the oxide zone trickle downward until a reached, usually at the ground-water level, where no more O is availal this reducing environment, the metals are deposited as secondary su According to L. C. Graton, secondary copper sulphides are deposited invariably by the replacement of other sulphides (16).

Replacement of other sulphides depends upon the relative solubilities; a sul lower solubility will replace one of higher, or, since FeS_2 is relatively more solu CuS, the CuS will replace FeS_2. Relative solubilities of the common sulphides in ing order are: HgS, Bi_2S_3, Ag_2S, CuS, PbS, NiS, CoS, FeS_2, ZnS, and MnS. He would not expect to find zones of secondary MnS or ZnS, because of their relativ solubilities, but would expect zones of secondary CuS and Ag_2S, because they tively less soluble than many common sulphides. Secondary CuS and Ag_2S are commonly encountered; if there is a gossan with Cu stains, an enriched zone of se CuS may be expected, if erosional and climatic conditions are favorable.

Inferences as to completeness of enrichment. This depends up

(a) **Rate of oxidation.** The rate at which material is released from the oxidi depends chiefly upon rate of erosion, length of time involved, climatic conditio meability of the rock, and topography. RATE OF EROSION. Ores are first brough reach of oxidation by erosion of overlying rocks. If erosion removes the top of the faster than it can be oxidized, no oxidation, and consequently no enrichment, res oxidation proceeds faster than erosion, oxidation will be halted by the ground-wat because the latter conforms approx with the topography and is depressed at sa

Character of primary minerals. If the mine workings are in the enrichment, the nature and value of the ore that will exist beneath may ferred by determining the kind and abundance of the original sulphide r by the secondary ores. For this the microscope is necessary. If dete that the secondary sulphides replace lean FeS_2, then lean pyritic material expected beneath the secondary zone; if they replace galena, bornite, and pyrite, then valuable primary ores may be expected.

STANFORD LIBRARIES

Tracing by panning (Sec 31, Art 5) may be used in a similar way. panful of dirt should be taken each time, so that results will be roughly tative. The mineral obtained is weighed and kept in numbered bottles, ber and wt of each trace being entered on the map. Blanks should be as carefully as good showings. Having no exposures to guide the work, can be done systematically at corners of squares. Panning along expo crops, or below probable location of drift-covered outcrops, is the cheap of finding oreshoots and determining their length.

Trenching. For a single orebody a series of trenches is usually dug at intervals, at right angles to course of outcrop. Probable extension of should be staked on the ground as a preliminary tance between trenches is determined by type body and depth of soil; they should be close en determine aver width and value of outcrops and missing oreshoots. Trenches over the latter ar together than on barren areas.

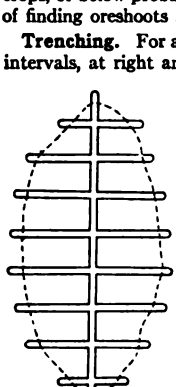

Fig 40

The first trenches should be as far apart as possi generally reduces number, length, and cost of inte trenches. It is more satisfactory to follow narrow out trenching along them. In shallow soil not more than 2 deep soil not more than 4 men, can be employed to adva trenching both ways from a single exposure (19). Fig 4 general arrangement of trenches on outcrops of large orebodies, planned to avoid high cost of complete st Where large drift-covered areas are explored for su mineral, trenches are usually dug along the sides of 50 to 200 ft apart. First work consists of 1 or 2 long t which give information as to geology, depth of soil, e generally divides area into favorable and unfavorable Good showings are explored first. If there are no surface indications, systematic started where the soil is shallowest; deep trenching is usually done last (see Cobalt,

Test pits for systematic surface exploration are spaced on corners of squares. Principles involved in their location are same as for boreholes (Art 8).

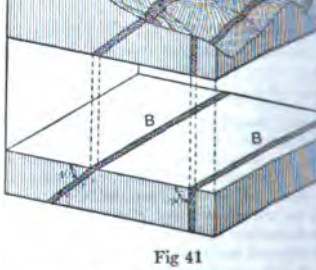

Fig 41

Summary of results. All exposures in exploratory openings are measured and sampled; widths, assays, and any further geological data obtained should be entered on the map, and geological cross-sections made where necessary to interpret structure. Results of shallow exploration may often be summarized by computing from area of orebody exposed the tons of ore per ft of depth. Depth to which the known orebodies must continue to repay estimated cost of development and equipment and yield a profit can then be calculated. This figure, compared local geology and type of orebody, furnishes a measure of the risk involved

Migration of outcrops. With unwarped veins, beds, faults, and cont dipping 90°, the outcrop is in a straight line (the strike), regardless of topogr (Fig 41, *A*). Outcrop of such deposits on flat topography is also a straight

In 1914, on La Rose property, the soil was shoveled off an area of several acres, i 20 ft wide; distance between strips was made as small as possible, determined height to which men could throw the dirt. With an aver depth of soil of 1.9 ft, th cost 37.2¢ per cu yd.

Witwatersrand, South Africa. Silicified conglomerates carry Au, and as members of a series of sedimentary rocks. The auriferous "banket" dip at 16 to 90°. Faults complicate the work of locating outcrop extensi places. "The surface is first examined to locate one or more beds of sand with which the reefs are conformable" (25). Topography is closely rela the geology; hard beds form ridges and, in some cases, streams follow fault In shallow soil, indications of the character of underlying rocks are obtaine ant hills; over banket these have generally a yellowish gray color, over dikes they consist of red loam.

Trenches are dug at right angles to the strike of the formation at regular int One trench near middle of property is continuous; the others are made only wh central trench shows that a reef is likely to cross. At each point where reef is fo small shaft is sunk deep enough to provide samples from points unaffected by alteration. In deep soil a small shaft is sunk into solid formation, and a crosscut to give a section of the rocks; or 2 or 3 shafts are sunk and connected by cro Values are remarkably persistent and fairly uniform over large areas of reef; hence, exploration gives reliable indications of conditions at depth.

Clinton hematites occur as stratified beds in the Clinton formation (Si age), all along the Appalachian Range, and also in New York, Kentucky Wisconsin. The beds vary in thickness from a few inches to 10 or 12 ft; the subject to all the irregularities of sedimentary rock beds (Art 5; also Sec 2, Ar

holes. Pits are better under such conditions for both prospect exploration, because of the more accurate information they afford. rock, small shafts often cost less than either churn-drill or core-drill shallow depths (20 to 50 ft). This is true only where no timberi quired and water is absent. In soft porphyry at Ajo, Ariz, 4 by 6-ft shafts, 50 ft deep, cost less than diamond-drill holes to same depth (2 cost of moving and setting up drills is largely responsible for the high co of shallow boreholes. For hard rock in general, and for greater depth rock or alluvium, the cost of boring per ft is 0.2 to 0.5 that of smal SPEED. Boring has little advantage over test pits for shallow work (20 in dry surface drift requiring no timbering. In rock, and for greater d alluvium, speed of boring may be 3 to 10 times that of shafts or other unde openings. Presence of WATER increases cost and decreases speed of unde openings, but does not interfere with boring. Boring is therefore pe applicable to prospecting and exploration in water-bearing formations POSE OF WORK. Many boreholes are made merely to locate strata or o preliminary to sinking or driving to or through them. Thus, in the Clin ores of Alabama, diamond-drill holes are bored at distances of 1 000 to from the outcrops, to locate the ore bed and anticipate the effect of f location of shafts and other mine workings. Similar cases occur in ma mines. On the Rand, also, the reefs under deep-level properties are loc diamond-drill holes before working shafts are started. SPEED VS COST. last-named cases, speed and cost are paramount factors, samples of t body are secondary objects, and boring has an advantage over shaft which increases with depth of the deposit. At the other extreme is th of detailed exploration to determine tonnage and aver values, in which c speed are subordinated to the necessity for accurate samples. In this c type of orebody determines the choice.

Underground openings always give more accurate information and samples, vantage can be taken of the speed and cheapness of boring in orebodies like the iron ores and the "porphyry coppers," where values are uniform over large areas, gradually from point to point. So much work has been done in some districts, Missouri and in certain placer deposits, that empirical factors have been determ correct inaccuracies due to boring practice and to irregularities of the orebodies

Boring from underground points by diamond drills is done in many in searching for parallel orebodies, or to locate the walls of wide orebodi

At Alaska Treadwell mine in 1913, 4 318 ft of holes were thus drilled to outline of the deposit (28). Rocks are hard diorite, quartz, and greenstone, and soft sl taining quartz stringers. A high core recovery was obtained; 90% in one horiz ho ft long. The information was therefore accurate. Drifting and tunneling wou taken 4 times as long, at a cost of $8 to $12 per ft. Cost of drilling was $1.62 to $ ft. Miami Copper Co did 2 714 ft of vertical diamond drilling from underground in 1912 and 1913 (29). Rock was silicified schist, broken into small pieces by fissu individual pieces being very hard. The holes caved frequently and were difficult and sample; less than 10% of the core was recovered. Cost, $5.44 per ft; speed 5.5 ft per 8-hr shift. These examples show that the advantages of boring are in very difficult formations. Fig 47 shows radiating diamond-drill holes for pros at the old Silver Islet mine, Mich. Such holes explore large areas much more and quickly than is possible with underground workings.

Boring has a special field in prospecting for oil, gas, salines, and sulphur, where th hole is used subsequently to conduct the mineral to the surface. For prospecting swamps, lakes, rivers, or deposits of quicksand, boreholes have no competitors. holes are sunk from solid ground, or vertical holes from boats or through the ice in

In remote districts the cost of transporting boring apparatus is generally prohi except for shallow prospecting where hand drills can be used. It should be note borehole results are susceptible of more accurate interpretation in districts where the

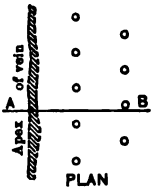
STANFORD LIBRARIES

For detailed exploration of flat massive deposits, drill holes are located on c squares. A systematic arrangement is essential, to secure impartial samples a intervals and simplify subsequent calculations of tonn aver values. Interval between holes is a matter of j based on type of orebody. Questions of cost urge that spaced far apart, but accuracy demands that the int limited to a distance over which it is safe to expect the or continue without marked irregularities in form or ten Art 11 for spacing used in different localities.)



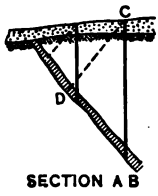


Fig 50

Fig 51, from R. V. Norris, shows one method of diamond-drill holes used in the Penn anthracite fields termining position and thickness of folded coal seams in which holes were drilled is shown by their number 14 was required to interpret data from 12 and 13; s hole 17 was drilled to correlate results from 15 and 1 face geology and outcrops are valuable aids in con such sections. In the Wyoming and Lackawanna Penn, coal seams often outcrop under present or valleys, filled with wash to depths of 50 to 175 ft. borings are made on corners of squares to determi ness of rock cover; size of squares varies from 100 ft, depending on this thickness and on irregularity of surface.

Prospecting for oil. First holes are generally loca reference to geological structure. Underground reserv occur in connection with anticlines, monoclines, synclines, and faulted zones in fields. "The area that can be drained by one well is variously estimated at f

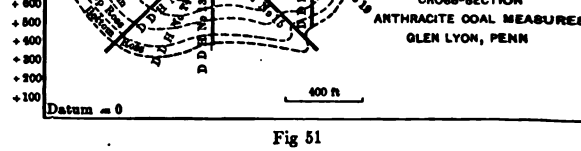

Fig 51

to six acres" (31). L. G. Huntley (32) says: "In spacing wells the utilizatio movement of the oil in a pool and the thorough draining of the maximum an territory with the minimum number of wells are the main considerations. As re first, the wells should be spaced closer together across the dip of the formation th the dip. In many fields the territory is divided among a number of operators, ea ing to extract the most oil possible before his neighbor has a chance to take usually results in the holders of small leases drilling many wells close to bounda forcing the lessees of surrounding land to drill well for well in order to prot own property. No attention is paid to the proper spacing of wells, nor to the effect of one well on another. When large operators control sufficient acreage, the practice in the older fields is to space wells from 400 to 500 ft apart."

Theoretically, if oil wells are spaced to give the same drainage area, they shoul ranged as in Fig 52. Table 6 gives spacings for use with this diagram.

Drill roads are a serious item of expense in swampy districts, and where the top is steep or rough. Standard rigs and diamond drills (except Missouri type) are m wagons requiring roads about 7 ft wide. For traction churn drills (Keystone N Star No 23), used in porphyry copper districts, hillside roads are made 9 ft wid solid. The fill is relied on only in case the machine skids. Max grade advisable which is also about the limit for teams hauling fuel and water. Traction drills c

Single holes, while valuable for determining position of an orebody, give no info
as to dip or strike, and often furnish erroneous values for thickness. The use of
ing wedges (Sec 9, Art 17) in deep diamond-drill holes, for getting a second sectio
formation from the same hole is a cheap means of securing additional data. Fo
of deflected diamond-drill holes see Sec 9, Art 17. A case of error from single h
occurred in districts such as the Missouri and Wisconsin zinc fields, where ch
holes following rich vertical stringers were taken to prove the existence of thick
bodies.

9. Sampling Boreholes

Accuracy of sampling depends largely upon the character of the r
drilled. Diamond drills give accurate samples in hard rocks where core r
is complete. Accurate samples are also obtainable by churn drills
grained, unconsolidated material, where casing pipe can be driven ahead
drill bit or sand pump.

Soft, broken formations which cave in the hole are most difficult to sample.
the efficiency of the diamond drill decreases both for drilling and sampling, an
drills are commonly used. Vugs, crevices, and brittle sulphides make sampling
Cores are more satisfactory than churn-drill sludge for determining geological det
careful panning of churn-drill cuttings generally makes it possible to locate ch
formation or mineralization within 2 or 3 ft. In coal, cores are necessary to g
rate widths, to locate partings and to secure correct analyses.

Length of samples taken from boreholes varies from 6 in to 10 ft
length, 5 ft. In soft, caving ground, or where mineralization is irregula
lengths are advisable for accurate work. In firmer ground with uniform
the longer lengths give adequate information and save expense for sampli
assaying. Calculations incident to large-scale boring are simplified by
samples in 5 or 10-ft lengths.

Diamond-drill samples consist of core, or sludge, or both. Where co
cores are obtained they are assayed, or the values estimated. In soft,
rock, where core recovery is low, the sludge must be saved and its assay co
with that of the core. Fine sludge is often difficult to catch, but al
be saved when drilling in ore which is near the merchantable limit of va

Barrels are used for settling sludge in some districts (Art 11); in others, SLUDGI
are made on the ground. Fig 55 shows a standard sludge box (36). Fig 56 sho

rrors in diamond-drill samples are sed by caving ground. Remedy is to ent the hole, or to ream and case. Sludge lso lost in crevices when all water does return to surface. Putting bran or man- into the hole will sometimes stop this loss. L. Botsford describes another source of r (38).

hole at a Lake Superior iron mine passed ugh following strata: soft slate and pyrite, to 215 ft; banded ore and chert; 215 to 470 oft iron ore, 470 to 545 ft; black slate, 545 to ft. Cores from soft ore assayed 5 to 8% more showed a trace of sulphur; the sludge ran lt ran 5.2% Fe; sludge, 40 to 50% Fe. By them at normal speed for time necessary to much sludge was produced as when drilling ound not caving so badly as to interfere with aterial from walls of hole to salt the sludge.

STANFORD LIBRARIES

Persistence of values in sludge below ore horizon, or "drag" of values (see E samples, below) may be caused also by a low velocity of water current rising the rods.

G. W. Thomson (39), in drilling 4 holes in the Porcupine district, Ontario, fo drag of values as shown in Table 7. Orebody consisted of auriferous quartz strin lenses in schist, the latter carrying no Often the only core recovered from a consisted of short pieces of quartz of a c length of not over 8 in. Values in the sl not correspond with the richer sections of t but appeared 5 to 10 ft below. Drag o was roughly proportionate to the depth at w was cut, and little trouble was exp from caving. Water supply was small, of rising current being from 6 to 8 in

Table 7

Hole	Depth, ft	Drag, ft	Angle of hole
1	320	15	76°
2	705	25	76°
3	655	15	90°
4	1 155	35	90°

Theoretically, it takes about 75 min for a current of 8 in per sec to raise a quar 0.08 in diam from a depth of 700 ft. These conditions would cause the larger and particles of sludge to hang back and appear later than the corresponding core. I tion as to amount of caving, contamination of sludge from walls, and loss of sl crevices can be obtained by weighing or measuring sludge from a sample run, and ing result with calculated wt or volume. This gives an index of reliability of the and shows where casing is necessary. Volume of sludge: cu in = $0.7854\,(LD^2 -$ where L = in drilled, C = core recovered, in; D = diam hole, in; D_1 = diam of

Combining core and sludge analyses. Following methods are u diamond-drill samples: (*a*) Core and sludge from a run are combined and a giving correct results when the sludge is all from the sample run in qu (*b*) Core alone is assayed; correct only when complete core recovery is made, which is rare. Sometimes value of core is estimated from its appearance (Art 11, S E Missouri). On the Rand, cores are split longitudinally; one half is assayed and the other filed for reference. (*c*) Sludge only is assayed; correct only when none or all of the core enters slud being ground up in core barrel. (*d*) Core and sludge are assayed sepa and an arithmetical average taken. This is incorrect, because volumes and sludge are unequal. (*e*) Core and sludge are assayed separately and values combined in proportion to their volumes. This gives correct r also the cores may be split and one half kept for geological study. (Sam Table 8, were taken in 5-ft lengths.)

bining Core and Sludge Assays

STANFORD LIBRARIES

H. L. Seward has constructed the diagram (Fig 58), from which values of $\frac{C}{L}$ be obtained for all cases where the sample run is 5 ft or less. When ratio b and L is less than 0.1, effect of core assay may be neglected, and assay of sludge as the aver.

Churn-drill samples (see also Sec 9). With hollow-rod drills, usi for flushing, samples are caught as for diamond-drill sludge. A sand pum with rope drills. The 6 to 10-in bits employed with these drills produ samples. At Miami, in a 5-ft run, a 10-in bit cut about 450 lb of rock; bit, 260 lb; 6.25-in bit, 180 lb (41). Practice in handling these large of material varies. Water and thin sludge are sometimes wasted, a and heavier cuttings dumped into a bucket for assay. This results in a of slime and serious errors in assay, especially when drilling in brittle s

Keystone Driller Co recommends that the sand pump be discharged into shown in Fig 59, built of 1-in surfaced lumber and set on low horses in from

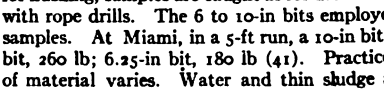

Fig 59

The partitions are set lo tween strips nailed to sid for removal when clea Sludge is dumped into the partment. After settling, drained off through plug far end of box. Remain and water are swept out through large plug hole into a tub or pails, and dried Good sampling practice for churn-drill work has been developed in the porphy districts, where the numerous samples taken and necessity for saving chalcocite slime make this work difficult.

At Nevada Consol Co, Ely, Nev, all sludge and water were poured directly into galvanized-iron wash tubs, and dried over a slow fire to avoid roasting the sulphides. A 5-ft sample required 4 tubs. In other districts, the sand pump is dumped into a launder containing split dividers, built like the Jones riffle sampler (Sec 30, Art 1).

L. S. Cates furnishes drawings of a splitter used by Ray Consol Co. It consists of a launder (Fig 60), into which the pump is dumped and which in turn spills into the splitter (Fig 61). Fig 62, 63 are drawings of the riffles. At Ray, the last split (about 40 lb) is dried for assay. Five tubs are provided for each drill. Samples are taken in 5-ft sections. Sampler keeps a record and pans sludge from upper portions of hole. When specks of mineral appear, the 4 previous samples are dried, so that assays of ground 20 ft above first visible mineral are obtained and useless assaying and drying avoided (42). Similar devices are used in other districts, giving a final sample containing 0.25 to 0.0625 of the total cuttings in a sample run, depending on number of splitters used.

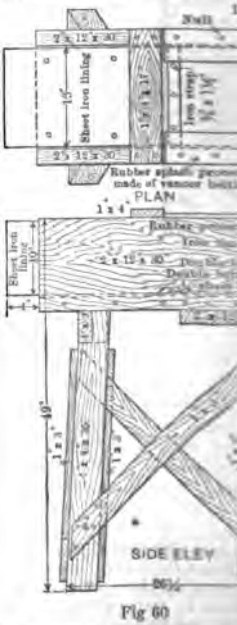

Fig 60

Savannah Copper Co, Burro Mtn district, N M, dried samples in an assay office at a distance from drills. If sludge showed visible mineral, it was reduced in splitter to about 4 gal; if not, it was cut to 1 gal. Final samples were put into 1-gal milk cans, with tight-fitting covers, in which they could be transported in wagons without loss (43). One sampler did for 2 drills, kept notes and checked drillers' measurements of depth.

splitters, and tubs must be scrupulously id salting succeeding samples.

Errors in churn-drill samples, besides hose due to careless handling of sludge on urface, may occur as follows: (*a*) Caving of alls of hole at some point above sample. his results in high or low assays, depend- g on whether cave takes place in rich or arren material. (*b*) Caving of walls of hole t point where sample is being taken. If ave is all from a rich streak, sample is false.

ing ahead for next sample. This procedure is costly and offsets advantage of chu in both cheapness and speed. Also, for reaming and handling casing in deep hole wheel is required, which is not usually on portable churn drills. An approx to above procedure is obtained more by starting hole with a large bit, ca soon as sludge shows mineral, and c ing hole with a smaller bit. When ca serious, another casing pipe is inserte the first and drilling is resumed wi smaller tools (Art 11, Porphyry co In any given district, practice genera resents a compromise between cost an lute accuracy. Pains are taken samples accurate enough for the p beyond that, cost of reaming and ca avoided.

Another error in churn-drill sampl curs through failure of sludger to pick cuttings. Experiments have been m determine loss from this source in plac ing. A piston (vacuum) pump in goo should be used. I. J. Stauber, while in Burro Mtn district, N M, made it a bail not less than 15 times after each run (43). Fixed rules based on expe should prevent error from this source. Churning action of tools may produce a con tion of values in sludge in hole. At Ely, Nev, it was found that the first bailerfu drilling ahead assayed higher than succeeding ones (45). This causes no error if all b for any advance of hole are put into same sample. In churn-drill holes, values som drag or appear in sludge obtained from points below ore horizon; caused by dislod of mineral from walls of uncased holes; or it may be due to incomplete recovery of by pump. In latter case, serious errors may result in interpretation of both thickn aver value of orebody.

Borehole results should be checked by means of shafts or raises at v intervals, especially in new districts and where they are to be used as a ba calculating tonnage and aver value.

10. Boring Records

Forms are needed for keeping costs, and for preserving sampling an logical data. Fig 64 shows typical cost-keeping form for diamond drillin 65, a similar form for churn-drill work. Fig 66 is an admirable daily record Fig 67, 68 are forms for summarizing drilling, geological and sampling d connection with Fig 64 (36). Fig 69, 70 are combined forms for underg diamond drilling; the smaller is for the foreman on each machine; head makes up the larger form, which is filed daily in chief engineer's office (4

Printed forms are preferable to notebooks, as they secure uniform data. In smal churn-drilling, the sampler's field notes are often recorded in an ordinary surveyor's sit book. The hole is drawn to scale on one page, and rock formation, changes in gr depths, water-level, character of mineralization, and sample numbers are entered in p position as they are obtained; the opposite page is used for explanations and other These notes are transcribed into a similar loose-leaf book for office use, in which are also recorded. Complete detail is essential in interpreting results. Besides the records should include: date of starting and finishing hole; total depth; location o elevation of collar; time for casing; names of drillers, samplers, and helpers (see also S

Platting boreholes. Drawings of drill holes, showing formations and po and assay of ore, are often necessary for intelligent computation of aver va

lost core; character of lost core as determined from sludge may be noted on the stick For storing large amounts of core so that they will be easily accessible for observ narrow shelves may be supported at intervals of 1.5 in on the sides of A-shaped frame

11. Examples of Boring and Sampling Practice

Porphyry coppers. These orebodies are large, low-grade deposits of c minerals (usually chalcocite), disseminated in altered and shattered mon porphyry, granite, or schist. They have large horiz dimensions and are ov by leached zones (capping) varying in thickness from 0 to 600 or 700 ft. Atte was first drawn to some of these deposits by favorable surface indications; c were discovered while working higher-grade deposits in their vicinity. range from 1.5% to 3% Cu; lower limit is a commercial one.

Boring practice on these deposits in different districts varies only in minor d Holes are bored on corners of 100 to 400-ft squares; most often, 200 ft. Dri results are checked at intervals by test pits, raises or winzes, and by drifts run on c nate lines to show variation in copper content between holes. Table 9 shows t examples of this type of orebody, and relative amounts of boring and underground done by different companies, before actual production began. An indeterminate p the footages given for underground work at Miami, Ray, and Inspiration represen velopment work preparatory to mining; figures for Ajo cover exploration work Most boring has been done by steam-driven churn drills. Traction drills, Keystone Star No 23, or Cyclone drills of corresponding size, have proved satisfactory. Expe shows that economic limit of depth for this size of drill in these formations is 600 to At greater depths, cost per ft of hole increases rapidly. For holes up to 350 ft depth corresponding in size to Keystone No 3 are cheaper, lighter, and large enough. F tails of churn-drilling practice on the porphyry coppers, see Sec 9, Art 3, Tables 9, 13, 14, and 15; for churn-drill sampling practice, see Art 9. Webber (33) notes var in assay between drill samples and those taken from check raises of as much as 0. ore averaging 3%. H. A. Fuld (49) reports that "where raises have been cut aroun holes, the ore from the raises averages several tenths higher than the results from

l chiefly to loss of slime in crevices. Annual that complete mining of representative areas of 5% of the total estimated copper content from

STANFORD LIBRARIES

Chile Exploration Co, Chuquicamata, Chile. P. Yeatman and E. S. Berry furni lowing data on drilling from beginning of work, April, 1912, to Oct, 1914: High due to extraordinary expenses and troubles incident to starting work in a remote At first there were numerous small difficulties in getting fuel to drills; water had hauled 2 miles by mule team to an elevation of 1 000 ft, while pumps and pipe line being installed. Delays during first 6 months' operatión, due to late delivery of parts from U S, caused shutting down of some drills for weeks at a time, while wi drillers and helpers continued. 11 holes were over 1 000 ft deep; many were betwe and 1 000 ft. 8 churn drills were purchased, costing, with necessary repair parts, de on property, about $67 000, or $1.47 per ft of hole drilled; this cost is not included in

Miami Copper Co, Ariz. A little underground diamond drilling was done i from 570-ft level; cost, $5.44 per ft; speed, 5.5 ft per 8-hr shift (29).

Ajo Copper Co, Ariz. Diamond drills used exclusively. J. C. Greenway an Joralemon furnish following details: When work was started, it was decided to dril ft of hole on most favorable showings, to see whether property had possibilities of a mine. Diamond drilling could be contracted at $4.75 per ft; no churn-drill cont were available. The limited time required operation of 2 drills. Cost of buying 2 drills was $8 000; cost of churn drilling was estimated as $3 per ft. Assuming sa costs equal for both drills, and allowing nothing for 2 churn-drill outfits at expira work, diamond drilling would save $5 375 on 1 500 ft of hole. These factors, con with risk involved, led to choice of diamond drills. They gave accurate samples, a results warranted further exploration. To secure uniform sampling data, work wa tinued with diamond drills at contract price of $6 per ft. Extremely rough topog which would have prevented construction of drill roads, also influenced choice of

Holes were drilled on corners of 200-ft squares; company men did the sampling. percentage of core was recovered, because of fractured nature of rock. Drill hole sampled in 5-ft sections. All sludge was caught in barrels and settled, water dec and sludge dried and quartered to 3 or 4 lb. Small samples of core and sludge fro 5-ft section were kept for reference. Sludge and core assays were combined fo figures. Shafts, 4 by 6 ft, aver depth 50 ft, were sunk to check drill hole results. ing was done by hand drilling, with Mex and Indian labor. Muck was sampled as were sunk; later, groove samples were cut on all 4 sides of each shaft. A little ing was done on coordinate lines, to show variation in copper content between adj holes, and some raises were put up on drill holes from drifts. Two years were sp doing the following work; 84 diamond-drill holes, 200 to 1 000 ft deep, total, 23 17 1 059 ft of shafts for checking drill holes in carbonate ore; 175 ft shafts for checkin holes in sulphide ores; 2 721 ft shafts in advance of drilling; 1 513 ft drifting in su ores; 142 ft raises. Calculations based on this work showed about 40 000 000 ton Shaft samples in carbonate ore averaged 0.005% lower than corresponding dri samples; shaft and raise samples in sulphide ore averaged 0.05% lower than dri samples, and drifts in sulphide ore averaged 0.26% higher than values indicated by holes at corners of blocks. (This remarkable agreement appears to be due to un character of ore, rather than to any inherent accuracy in diamond-drill samples. Au Table 11 gives cost of drilling, based on 17 310 ft of hole, and cost of sinking 4 000 shaft; superintendence, office and engineering expense are not included. Note tha cluding sampling, a 50-ft shaft at Ajo cost less than a 50-ft drill hole (27).

low floor of shanty, in such position that there mple without moving box. Connect a tee to from it to nearer end of sludge box, at such sludge box and just rest upon its top, and of

STANFORD LIBRARIES

such length that it will not project more than 1 in beyond edge of box. The pi not exceed 2 ft long; if longer than 1 ft, it must be split on top for 1 ft nearest slu so that sludge collecting in pipe may be seen. Set box level, so that water will evenly across whole width at far end, and wedge partition firmly in close cont bottom of box. Top of partition should be 1 in below water level. Box is now receive sample. While drilling, care must be taken that no water from drill hol around or over the tee, except through pipe leading to sludge box. There must b from box and the plug at the end must be tight. Sludge samples are taken for e drilled, or less, preferably from even 5-ft intervals; that is, from 460 to 465, 46 etc. Whenever a sample is to be taken, drilling must be stopped and hole wa clean. Pipe leading to sludge box must be cleaned out into the box, and pu then be stopped or tee turned so that water will not discharge into box. Carefull partition in box, so as not to stir up sludge. When sludge is settled, siphon o water, keeping end of siphon near surface of water, and not disturbing or drawin fine sludge from the bottom. Siphon may be allowed to flow until sludge beg off with water. Take out hose and thoroughly mix sludge in box to a mud, whic placed in a pan on a boiler to dry. Pan must be at least 8 by 12 in by 1 in deep, bottom, and is thoroughly cleaned each time before a sample is put into it. I water cannot be drawn off, without disturbing sludge, so that sample can be c in this pan, use a larger pan. When sludge has been cleaned out, remove plug at en wash out with a pail or two of water, then replace plug and partition, and drillin started again. Sludge must be labeled, giving depths between which the sa taken, and must all be saved and turned over to inspector when drilling in iron fo or in other ferruginous or red material. While drilling in material from which should be taken, if water is lost, or if sludge does not come up with water, or if taminated with material caving from upper part of hole, drilling must be stop hole is put in such condition that good sludge can again be obtained, or until permits drilling to proceed. Whenever drill runs into or out of ore, 1 ft or more th ing must be stopped, and sludge box cleaned out, without waiting to complete run. When drill runs out of ore, continue taking and saving sludge samples for a ft, no matter what the material, so that it may be determined whether ore is c

Core. Keep core separate from sludge; each time core is pulled, label it wit between which it was recovered. Each run of core is kept separate, and all c and turned over to inspector. When core is pulled, if it is found that more is sa in proportion of 1 ft of core to 10 ft of drilling, sludge box must be cleaned witho to complete the 5-ft run, and the sludge labeled and saved separately. If slud shorter distance than 5 ft is in box at end of shift's work, and if less than above p of core is saved, sludge may be left in box, provided shanty is locked and box is in from outside. If anybody can get at the box, and if there is no watchman, slu be removed from box, dried, labeled, and placed with other samples.

Mesabi Range, Minn. Ores are massive, flat deposits of hematite, horiz extent as compared with their depth. Orebodies are generally l 200 ft thick, and may extend laterally for a mile or more. They are by soil and glacial drift averaging 65 ft deep. Fig 83 (Art 12) shows a section. There are few surface indications of ore. Early practice was test pits through the drift, and as far into ore as permitted by facili cost for handling water, hoisting, and ventilation. Exploration was c from bottom of these pits by boring. At present, both prospecting and tion are done entirely by boring from surface, which is cheaper, quic avoids dangers from numerous open test pits.

Boring practice. Both churn drills, with perforated bit and hollow rods, and drills are used (35), with water under pressure for flushing cuttings to surface drills are used in surface drift, soft rock, and ore; diamond drills in taconite and o formations. Holes are churn-drilled to hard rock and cased with heavy 3-in. l pipe. Diamond drill is then used until ore is struck or hole abandoned. If more of ore is found below taconite, hole is enlarged by blasting, a 2-in casing put in, an continued with churn drill. Casing is kept close to bottom of hole. Land is h acre tracts, and for preliminary prospecting 5 holes are put down on each tract. of the holes varies; common arrangement is to put 1 hole in center and othe

space their holes about 500 ft apart. Fig 77 ts are being drilled for same parties. If ore is rily abandoned. 5 holes are not final proof; in ontaining 1 000 000 tons was missed. If ore is rdinate lines are exploration done , or 300 ft apart, conite to a depth hole in each 40- hich underlies all entirely by con- a reputation for

Southeastern Missouri. The disseminated lead ore occurs in flat m dolomite, at depths of 200 to 600 ft. Thickness of orebodies, up to 70 cover considerable lateral area. Overlying rocks are limestone and sh glomerates, and dolomite, free from chert. There are no outcrops; p ing and exploration are done by diamond-drilling from surface. Churn d used as auxiliaries to put holes down to bed rock through deep surf Geologic features indicate probable orebearing areas in a broad way.

Boring and sampling. H. A. Guess, Gen Mgr, Federal Lead Co, furnishes ing data (Fig 78) (See also Bib 55). "In extending the limits of known orebo only way to do is to feel along with the diamond drill until the full limits of ore defined. For this work, holes are close-spaced, usually 200 ft, sometimes 100 general prospecting for new orebodies, holes are spaced 400 or 600 ft or even furth in checkerboard fashion or in lines transverse with supposed strike of ore run. W is cut, detailed drilling is begun with spacing of 200 ft or less." Procedure va different companies. A solid bit is used until near expected ore horizon; then a with a 5 or 10-ft core barrel, until the hole bottoms in sandstone known to und orebodies. About 25% of total footage is cored. Lead content of cores is estima their appearance; one estimator is employed for 10 or 12 drills. Cores are assay sionally as a check. Throughout the mineral zone, all sludge is caught and ass check estimations and core assays. Sludge serves as a further record when a core part of a soft lead layer is ground up in trying to core it. Combined solid and drilling costs 60¢ to $1 per ft, average 75¢. Aver speed of drilling per 10-hr s solid bit, 60 ft; for core bit, 30 ft. Fig 78 shows outline of workings on one orebo

$$+ \cdots + L_n$$

is arithmetical aver of assays of samples.

STANFORD LIBRARIES

Average value and tonnage of an orebody is calculated from bor sults in different ways, depending on ore occurrence and information de

Examples. Iron-ore deposits at Moa and Mayari, Cuba, and placer dredg erties, are examples of surface orebodies with no overburden, and fairly regula For such orebodies, estimates are made thus: Let $V_1, V_2, \ldots V_n$ = aver valu of drill holes 1, 2, 3, . . . n; $A_1, A_2, \ldots A_n$ = respective areas of influence holes, sq ft; $D_1, D_2 \ldots D_n$ = respective depths of holes, ft; A = total area o V = aver value of deposit; D = aver depth; T = total tonnage; C = cu ft p place; n = number of holes. Then,

For holes spaced irregularly:

$$V = \frac{A_1V_1D_1 + A_2V_2D_2 + \cdots + A_nV_nD_n}{A_1D_1 + A_2D_2 + \ldots A_nD_n} \quad (2)$$

$$D = \frac{A_1D_1 + A_2D_2 + \cdots + A_nD_n}{A} \quad (3)$$

$$T = \frac{(A_1 + A_2 + \cdots + A_n)\,D}{C} \quad (4)$$

For holes spaced at regular i

$$V = \frac{V_1D_1 + V_2D_2 + \cdots}{nD}$$

$$D = \frac{D_1 + D_2 + \cdots + D}{n}$$

$$T = \frac{AD}{C}$$

Area of influence of a borehole is the area in which values shown hole are assumed to persist. Theory of averaging samples in general on assumption that values vary at a uniform rate between sample point assumption is met by so taking the area of influence of a hole that eve within it is nearer to that hole than to any other.

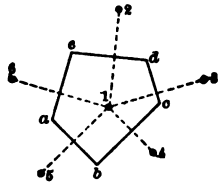

Fig 79

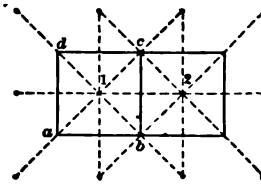

Fig 80

Fig 79 shows general case for holes spaced irregularly. Area of influence for is found by drawing lines 1–2, 1–3, etc, connecting hole No 1 with all those Lines *ab*, *bc*, *cd*, *de*, and *e* pendicular bisectors of lines 1–3, 1–2, and 1–6, res They enclose polygon *abcde* area of influence of hole N 80 shows same construction to holes spaced on corners o In this case, area of influen hole is a square (*abcd* for h the side of which is the between holes.

, on which 5 E-W sections and 7 N-S sec-tion *FF* of this orebody (sample analyses is made, showing superposed contours of

STANFORD LIBRARIES

surface and top and bottom of orebody. Usually, extension of ore bey hole in any section is arbitrarily set at a distance equal to depth of ore hole, and bottom of ore is assumed to be a line joining this point with of hole. The 2 sets of sections are checked against each other, and fro limits of orebody are outlined in plan (Fig 82). Three preliminary e are then made as follows:

(*a*) **Total tonnage** is computed from area of orebody and its aver depth. for wedge shape of edges of orebody, the line marked "limit of area for total ore (Fig 82) is drawn half-way up the slopes on margins of the orebody. Area en this line × aver depth of ore ÷ cu ft per ton gives total tonnage. Areas are measu planimeter, aver depth of ore is computed from borehole data, and cu ft per ton mated from tests and experience.

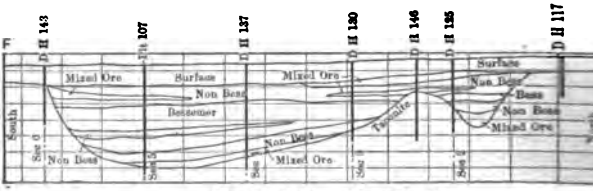

Fig 83. Section *FF* on Fig 82

(*b*) **Stripping estimate.** Proper BERM distance is laid out between edge of and toe of the bank or overburden; slopes of 1 : 1 or 0.75 : 1 are selected (depe character of surface drift), and intersection of this slope with surface contour is Aver area to be stripped (limit of area, stripping estimate, Fig 82) is taken as a way up this slope. This aver area × aver depth of stripping ÷ 27 = cu yd of

(*c*) **Possible steam-shovel tonnage.** With the aid of sections and combine map, a system of tracks is laid out for operating shovels and ore trains. This gi and size of deepest possible shovel excavation. Elevation at which each boreh be cut by this excavation is noted, and aver depth of ore taken out thus determin aver depth × area previously determined (total tonnage estimate) ÷ vol per ton tonnage used for preliminary estimates. Final or detailed estimates are made a

(*d*) **Graded-tonnage estimates** for securing relative tonnages of Bessem Bessemer and mixed ore. Two methods are used. In COMPOSITE-HOLE METH depth of ore of, say, Bessemer grade is first computed as arithmetical aver of Bessemer ore cut in all holes within area of orebody. If a hole shows no Besse it is included in the aver as zero. This aver depth × area (total tonnage estimat per ton gives total tonnage of Bessemer ore. Same calculation is made for othe Second and PREFERABLE METHOD is shown by Fig 82. From cross-sections, the of different grades of ore are worked out and plotted in plan, and planimeter ments are made of the area of each grade at each horizon. From these areas respective aver depths, volume of ore in each grade is computed. Plotting the different grades is intricate work. In the example, the taconite horse, shown i *FF* (Fig 83), cuts out roughly circular areas from 2 ore layers. Such areas are and subtracted from total area of the respective grades in which they occur.

(*e*) **Graded-tonnage estimates and aver analysis.** Tonnage estimates are the second method under (*d*). Aver analysis of ore in a grade is obtained by a drill-hole samples in proportion to their length (Eq 1 above). Products of sample per cent are locally called FOOT UNITS, which are computed for Fe, P, SiO_2, CaO, and S, or for such of these elements as are desired. "If for each ore-bear foot units are computed for each grade and these results added together, the respective total foot units for the grades in the orebody. Such sums are divide spective total feet of samples to give average analysis for each grade of the o TON UNITS is the name given to the products obtained by multiplying tons of a by its aver analysis (in Fe, P, etc). Aver analysis of all grades in the deposit is th ton units for each grade divided by total tonnage of deposit (Eq 2 above).

mmonly spaced on corners of 200-ft squares. tical cross-sections are constructed at right outlined on each. Usually there is some A. J. Sale (60) recommends that sections es (*AG*, *BF*, *DJ*, *EI*, etc, Fig 84), instead of etc), thereby increasing distance apart of ections closer together. STANFORD LIBRARIES

in orebody increases as lower-grade ore is included in it. A. J. Sale (60) gives a cou method of analyzing these variables. Before averages are made, assays of drill s are corrected for mill recovery, corrected values being called NET PER CENTS. Sets tions are then constructed to include on margins of orebody ore having minim assays of say 1, 1.5, 2, 2.5, and 3% Cu. Estimates of tonnage and aver value (ne grade) are made for each minimum net % used, and results plotted as shown in Curve of net production, in lb of copper, is computed from known points on cu tonnage and net mean grade. Interpolations made on these curves show at once th of including ore of any minimum net grade between 1 and 3%. This device is of limited to the special conditions outlined above.

13. Exploration by Shafts, Tunnels and Drifts

Underground exploration is undertaken where conditions prevent s work, or where surface exploration gives no information as to underlyin bodies. Art 5 contains suggestions as to location of openings with resp geology. General rules : (*a*) Keep workings in the orebody; (*b*) Do firs on best showings, to see whether or not they are superficial; (*c*) Do the as cheaply as possible on account of the high risk involved.

Narrow veins are explored as in Fig 86. On each oreshoot, a small has been sunk, following sinuosities of vein (see cross-sec *AB*), and drifts are each shoot. Depth at which drifting starts in such work is from 50 to 100

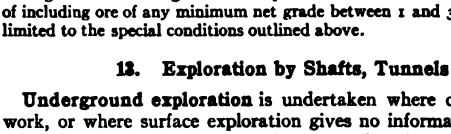

Fig 86. Typical Exploratory Work

depends largely on of surface alteratic level of ground wat is influenced by so local factors that general statements made.

Good showings in th may be explored with *R* or winzes *W*. In lo

shoots, raises may be put up at regular intervals. Workings are sampled and est made of tonnage and value of ore exposed (Sec 25, Art 12 to 15) as work progresse different times these figures, together with geological conditions, form a basis for juc as to whether: (*a*) prospect should be abandoned; (*b*) further exploration is war and, if so, its amount and character; (*c*) net value and amount of ore proved and w probabilities for extensions are sufficient to warrant systematic development and ment for the property. Further exploration would consist of deepening shafts and other drifts at intervals of 60 to 100 ft. WIDE VEINS are explored by same methods, but crosscuts are driven from wall to wall at regular intervals to det width, character, and value of ore.

Veins outcropping across a ravine may be explored with drift tunnel raises (Fig 87). Tunneling in general is cheaper than shaft sinking, an workings drain themselves.

Fig 87. Longitudinal Section in Plane of V

With STEEP TOPOGRAPHY there is great temptation to drive crosscut tunnels to intersect an orebody in depth (Fig 5, Art 1), lateral exploration being done by drifts, raises, and winzes as before. This involves a higher risk than where workings follow the orebody; the latter may be cut in a pinch and not be recognized; faults, and changes in dip or strike may cau tunnel to miss the orebody. Large amounts of water occurring near surface may use of crosscut tunnels for early exploration. Difficulties of such work should be nized; tunnels should not be far apart and there should be money enough to co work, if orebody is not cut at point calculated from its surface dip.

Tunnels *vs* shafts. Drift and crosscut tunnels can be driven fas cheaper than shafts. Wet ground increases this advantage, as a tunne the overlying ore by gravity, and eliminates pumping. Hoisting plant not required until operations extend below the tunnel level.

Crosscut tunnels prospect the country rock and may disclose para posits (Art 5). Drift tunnel is usually preferable, if a choice exists involved in driving crosscut tunnels is higher than for other method try; it increases with length of tunnel and its depth below known ore. unwise to begin development with a long crosscut before exploration ha an adequate tonnage of ore, and either proved or given strong geologi dence of its extension to the tunnel level.

Several long and deep crosscut tunnels have been driven, to provide drainage nomical transportation for groups of mines. They are justified when the sa known orebodies will amortize cost of tunnel at a profit during life of properties

Drift and crosscut tunnels serve mainly for extraction of ore lying above them must be sunk from tunnel level or from surface to develop deeper portions of a dep C. Hoover (20) points out that internal shafts require large excavations to accommod ing plant; also the latter must be operated by electricity or compressed air. Wh power is generated at the mine, saving is effected by placing the hoist on surface boiler plant. Combined cost of tramming and transferring ore to tunnel cars more than cost of hoisting the extra distance to surface. Questions of conver handling ore on surface may modify choice of method. Tunnels preserve their function after mining above them has ceased; surface water may be intercepte tunnel level, and the head on pumps at lower levels is reduced by difference in between collar of shaft and tunnel level. Saving in pumping may warrant the new and deeper adit, or the driving of a tunnel to tap workings already opened by even though the tunnel is used for drainage purposes only. Length of such a tunn it will pay to drive = present value of annual saving in pumping cost during prol of mine ÷ cost per ft of tunnel; for example, with power @ $60 per hp-yr, cost o ing @ $20 per ft, and a 10-yr life, it will pay to drive 600 ft of tunnel per 100 000 per day per 100 ft head saved.

Vertical *vs* inclined shaft. A typical example requiring a decision the two kinds of shaft arises in case of a pitching vein, as in Fig 88. An shaft is generally sunk in footwall (AB). Vertical shaft may be at CD either location requires more crosscutting than the inclined shaft, and fr standpoint the inclined shaft has an advantage which varies with dip of with depth. A greater length of incline is necessary to reach any level; this compensating advantage of the vertical shaft increases as the di flattens. Shaft AE always requires more crosscutting than CD; for total length of crosscuts is a minimum when $CF = FD$. Depth CD mus sumed in comparing merits of alternative locations. Factors to be conside

First cost. Vertical shafts cost more or less per ft than inclined shafts, acc local conditions and the way in which ground breaks. Sometimes drill holes in o other can be placed to take advantage of planes of weakness, thereby increasing s decreasing cost. Sinking very flat inclines resembles drifting; they usually cost ft than a vertical shaft of same cross-sec (see Sec 7). Cost per ft of crosscutting is same for either mode of entry. A comparison of total costs is made by appl costs to total footage of the different openings involved. For given depth and u of sinking and crosscutting, an angle of dip will be found at which the cost of han shaft CD (Fig 88) with its crosscuts is same as that of footwall shaft AB with its c on flatter dips, an inclined shaft entry is cheaper, and *vice versa*. Critical angle cases is about 70°. For all dips permitting a choice, a footwall vertical shaft A crosscuts cost most.

Cost of equipment. To reach a given level, a vertical shaft requires less hoist piping, wiring and timber, than an incline. Cost of surface plant is related to shaft in a very general way only; it should be determined for each alternative.

cal shafts is generally cheaper than in inclined
ven level is less; hoisting ropes last longer; there

also reduced surface tramming distance. The incline, which was begun when s
4 were about 500 ft deep, bottomed the shoot at between 700 and 800 ft; it was
doned and the shoot followed with shafts 2 and 4.

In case of a pitching oreshoot passing through the end line of a property, as at *EF* (Fig 97), the problem of entry on the adjoining ground is like that presented by deep-level mines. Position of oreshoots largely determines position of raises, as they are kept in ore to provide points of attack and ventilation for stopes (Art 20).

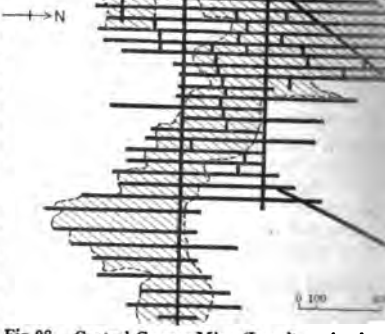

Fig 98. Central Copper Mine (Longit sec in plane

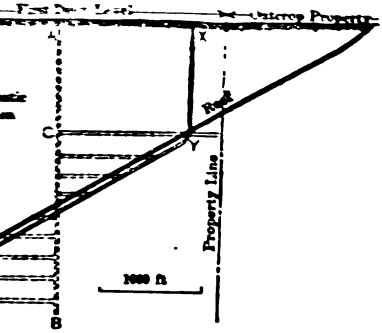
Deep mines (deep-level mines). Peculiar development problems arise where mining rights terminate at vertical planes passed through surface property lines. Fig 99 illustrates conditions on the Rand. Gold-bearing beds, locally called REEFS, extend depths. Dips vary greatly; in central Rand, aver dip at outcrop is 50 flattening to about 30° in depth. Properties worked from the outcrop a OUTCROP MINES; those covering adjacent extensions on the dip are k first row, second row, etc, of DEEP-LEVEL MINES. There are 3 modes of a deep-level property underlain by an inclined deposit: (*a*) A vertical sunk to the reef near the rise boundary, and continued as an incline in wall, the 2 parts of the shaft being joined by a carefully designed curv TURNED-VERTICAL or compound shaft (*XYZ*, Fig 99). (*b*) A CENTRAL V SHAFT *AB* is sunk, and the reef reached by crosscuts. (*c*) An arrangem

inclined parts of shaft are not directly con-
ne independent underground hoist, delivers



tcrop and Deep-level Mines, Witwatersrand

p a deep-level property. Other advantages, as
e: saving in crosscuts and raises, and ultimate
utility of shaft to any depth. Disadvantages:
cost of extra length of inclined section; slower
hoisting, due to necessity for slowing down at
curve; greater wear and tear on incline and on
ropes, especially around the turn. From stand-
point of first cost, choice is based on comparison
of inclined shaft *YZ* (Fig 99) and vertical shaft
CB; result is governed by dip (Art 16); the flat
dips of the Rand obviously favor inclined shafts
(20). Some engineers favor the central vertical
shaft for all cases (for further detail and differ-
ent points of view, see Bib 30, 70, 72, 73).

Factors of reduced speed and increased wear on hoisting rope, etc, become serious as depth increases, and, combined with mechanical difficulties in deep hoisting, have led Rand engineers to favor stage hoisting for depths over 3 000 ft. If proper storage is provided at transfer point, stage of a shaft, since both parts of it can be hoist-
osts of hoisting reported for turned-vertical
ormer; this is to be expected unless depth is
ystem fully utilized. A turned-vertical shaft
s was done in the case shown by Fig 100.

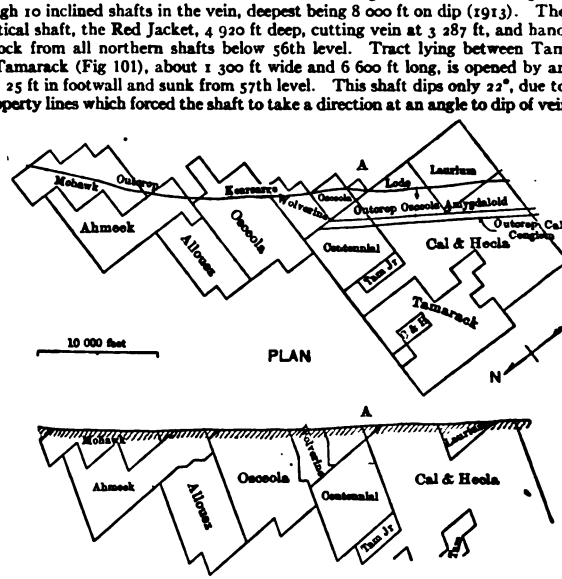
Michigan copper region. Fig 101 shows approx property lines of a group covering outcrops of Calumet conglomerate and Osceola and Kearsarge amygda Dip of beds, 37° to 38°.

Tamarack Co works the underlay of the Calumet conglomerate through 5 vertic ranging in depth from 3 409 to 5 308 ft (1913). No 5, the deepest, cuts the vein ft; bottom of shaft is over 1 600 ft horizontally from the vein. From the bottom of No 3 shaft (depth 5 253 ft) an incline in the vein is operated by a compressed- This was to save deepening the shaft and driving long crosscuts, which have high nance cost. Calumet & Hecla Co has worked this conglomerate bed for length through 10 inclined shafts in the vein, deepest being 8 000 ft on dip (1913). The a vertical shaft, the Red Jacket, 4 920 ft deep, cutting vein at 3 287 ft, and hand per rock from all northern shafts below 56th level. Tract lying between Tam and Tamarack (Fig 101), about 1 300 ft wide and 6 600 ft long, is opened by an shaft, 25 ft in footwall and sunk from 57th level. This shaft dips only 22°, due to of property lines which forced the shaft to take a direction at an angle to dip of vein



PROJECTION ON PLANE OF KEARSARGE LODE

Fig 101

cars are hoisted in this shaft and transported mechanically 1 500 ft on 57th leve Jacket shaft. This plan saved a very deep and costly vertical shaft.

Lower half of Fig 101 is a projection of property lines on plane of Kearsarge ve outcrops as shown and dips 34° to 42°. Ahmeek Co opened its property with 4 of which are sunk in the vein from outcrop. To develop northern part of propert outcrop is owned by Mohawk Co, 2 shafts were sunk, starting on angle of 80°; they curve on a 400-ft radius and enter the Kearsarge vein at 1 275 ft, on angl There are 3 levels, reached by crosscuts, above point of intersection of shaft a These 2 Ahmeek shafts start on surface close together; but diverge to N and W

Allouez Mining Co has also sunk 2 turned shafts to Kearsarge lode, starting fro at angles of about 80°. Depths to change of angle are 1 435 ft and 2 307 ft; tot 3 544 and 3 407 ft (1915). Both can be sunk to 9 400 ft before reaching pro (Fig 101). Tamarack, Ahmeek, and Allouez mines are controlled by Calumet Co. The turned shafts were sunk in the light of experience gained from the dee rack and Red Jacket vertical shafts and their long crosscuts.

Centennial mine has a small tract *A* (Fig 101), covering outcrop of Kearsage a right of way 100 ft wide connecting it with the large underlay property shown. these conditions a novel mode of entry was adopted. Two inclined shafts were in the outcrop, close together; southerly shaft runs straight down the dip; other is

ere it curves 15° to the north in plane of vein. t reverse at each end to keep the rope on idlers, The hoisting rope has shown greater wear than on ment is satisfactory (67).

ine, Cal, has a different purpose. A gold-quarts l shaft. Later a 1 630-ft vertical shaft was sunk ence continued as an incline to 5 850 ft, or 2 200 haul to surface by 2 370 ft, and its first cost is maintenance cost of a long incline through old is kind. Red Jacket shaft, of Calumet & Hecla s an auxiliary opening with similar purpose. It d maintenance cost of a 5 400-ft inclined shaft.

n inclined deposit, the upper parts of which are Choice is between vertical, turned-vertical, and depth to virgin ground and dip of deposit. Mt ne numerous factors to be considered. Orebody containing a concentration or vein of magnetite 24 to 40 ft; aver dip, 60° to 65°; country rock, o depth of 700 to 900 ft vertically. In 1914, it otwall shaft (dip 63°), 25 to 50 ft below deposit. tended ultimately to 1 800 or 2 400 ft. Reasons l ore pockets for a vertical shaft, because of the ng in the lean mineralized footwall zone; free- lue to mining operations; a vertical shaft to de- e 100 ft lower than, and 1 000 ft distant from, shaft would deliver ore direct to mill (74).

To secure economical handling, haulage t or change direction by easy curves, and mportance of these points varies with size ulage. Following are extreme cases:

Gilpin Co, Colo, the tonnage per shift from any id drifts properly follow the ore with little regard Rand, a main haulage level, 14.5 ft wide and ex- les), connects 2 shafts at a vertical depth of 2 200 all. It is planned for electric haulage to handle aulage ways are to be driven as required at inter- enings are the regular drifts on the reef. Similar ew Modderfontein and Modder B mines (75).

ment work can be planned to reduce pump- 6). Drainage also makes it desirable to the lowest point of flat-dipping or basin- en drain toward shaft and auxiliary sumps unction of lateral development is to drain es, like some Michigan iron deposits, this ent work done in advance of mining. New drain before extraction begins. This also ake pumping operations fairly uniform (76).

levelopment openings be run in duplicate. complete control of ventilating currents oints of entry are often required for venti- lation affects chiefly the location of raises lems until great depths are reached.

STANFORD LIBRARIES

18. Number of Openings

Determining factors. VENTILATION AND SAFETY demand at openings to surface; they are required by law in many districts. In meta stopes reaching the outcrop often afford an adequate second opening; lieries, rigid ventilation requirements compel at least 2 openings. Othe tions to be considered: (*a*) Required OUTPUT may be in excess of capac single shaft; this is unusual at ordinary depths, as a shaft can be desi handle large tonnages. In deep shafts, the time required to get men on shift through a single shaft is serious; this, together with time for h timber and supplies, greatly reduces ore-handling capacity. (*b*) SEPARA BODIES may require separate shafts; depending on their size, distance depth below surface, and surface conditions. Separate shafts are sunk t a saving over cost of entry from, and handling through, another shaft away. This is a matter of estimate in each case; size of orebody concern be sufficient to return excess cost of separate shaft out of the saving e Cost of shaft sinking increases with depth, that of drifts and crosscuts de hence, increasing depth should reduce the number of shafts and increa area served by each. Topographic or other conditions affecting surface port may prohibit separate openings; conversely, they may show a saving face over underground transport which alone will justify a separate shaft. statements apply also to veins in which several oreshoots occur, separa wide barren or low-grade areas. H. C. Hoover states that if cost per ft c sinking is 4 times that of drifting, through 1 000 ft of barren vein cost n than 1 shaft 1 000 ft deep (20). (*c*) OD OF UNDERGROUND HAULAGE. F is a diagrammatic section in plane inclined vein in a property of consid length. If ore occurs scattered thro

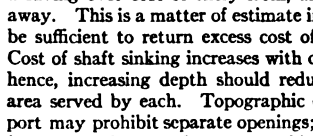

Fig 102

whole vein, question arises whether it is better to sink 1 central shaft *A*, or 2 *B* and *C*, placed at quarter points, or several shafts. This is determined by method of haulage on levels. Cost of hand tramming per ton increases with distance; there is a limiting length of tram beyond which a new sha save its cost; economic limits for animal and mechanical haulage are Tonnage produced per shift on 1 level affects method of haulage (Sec 11). small, it may be possible to install mechanical haulage on every second or third level, ore from levels above being transferred to the haulage level through winzes at distances apart which are within the economic limit of hand tramming.

Michigan copper mines are illustrations of properties covering long distances along the strike of persistent lodes (Fig 101). Hand tramming was formerly universal, and a shaft was sunk about every 1 000 ft along strike. There are instances of 2 shafts 600 ft apart reaching depths of over 3 000 ft. Table 13 shows aver hand ming distance in Calumet & Hecla and allied properties, from Jan 1 to June 30, 191

conditions; they also vary because some loading is
g. Recent shafts are farther apart; aver distance for
cy mine, with electric haulage, aver tram is 1 800 ft.

ere length of property along strike is less than 1 500
vas sunk; on longer properties 2 shafts were deemed
ıd for ventilation (25). Transvaal law requires 2
properties are as close as 1 000 ft, but usually 2 000
and, but labor is cheap. Many deep-level proper-
large areas (400 to 900 claims of 1.4 acres each);
between shafts is 3 000 to 4 000 ft (78). Occasion-

drift requires timbering, track, pipe, and ditches,

STANFORD LIBRARIES

which must be maintained during life of stopes above. Cost of shaft stations, a
or bins, can be reduced by concentrating haulage on alternate or third levels.
standpoint of first cost, a long interval between levels is desirable. TYPE OF O
High-grade, spotted or pockety mines require levels to be close together to avoid
orebodies; a wide interval in such cases also adds to cost of reaching and ex
scattered pockets. SUPPORT OF HANGING WALL. Levels sometimes form one side
left to support roof; allowable area of unsupported hanging wall then limits level
SPEED OF STOPING and character of ground are related factors; level interval sh
such that stopes are completed and abandoned within the time that they can be k
without undue maintenance cost. Thus, at Leonard mine, Butte, Mont, a 200-ft
in vertical, filled, square-set stopes increased cost and decreased speed of mining
upper 100-ft lift to an extent which warranted driving intermediate levels at 100-
vals (80). METHOD OF MINING. A retreating system, where stopes are started at
lines and abandoned as they are carried back toward entry, may allow a larger lev
val than an advancing system. Cost of maintenance of levels themselves gene
creases with the time they are kept open. This is again related to speed of sto
method of mining, and may determine the max interval. In small-scale work, on
high-grade oreshoot, the time required to stope one lift determines time available
ing and drifting through the shoot on next level, and consequently determines lev
val; such conditions arise in leasing. DIP OF OREBODY, if over 40° to 45°, allows
ore to fall by gravity to level below; if less than 10°, cars can generally be run
ing faces. In these two cases, the dip does not limit max level interval. On int
ate dips, if ore is shoveled to drift, the level interval should be small; for economy
of distance with other handling devices in flat stopes, see Art 92. REGULARITY OF
influences handling methods and therefore the level interval; an irregular footwall i
the limiting angle on which ore slides and always requires some shoveling; badly
deposits require levels placed to reach displaced blocks regardless of other factors

Economic level interval in any mine is a matter of experiment. The
levels are usually spaced farther apart than the upper, because early work
mines the mining factors, and reduces the exploratory function of these op

On the Rand the level interval in some properties has been increased to a s
extent. At Modderfontein B mine, ore is developed in blocks 800 by 1 000 ft;
Modderfontein, level interval is 500 to 600 ft, with footwall main haulage drifts
2 000 ft apart; at Brakpan mine, level interval varies from 300 to 1 200 ft. This
due to an attempt to cut down development cost, has not been uniformly successfu
made possible in these mines by: (*a*) very flat dips (7° to 10°), allowing cars to run
faces; (*b*) regularity of vein; (*c*) knowledge of reef characteristics, resulting in co
in the continuance of value and size over large areas (75, 79, 81, 82).

Raises and winzes. For following indications or exposures of ore up o
from a level, the location of raises and winzes depends entirely on ore occu
To determine outline and value of shoots, raises are often made at fairly
intervals. For this purpose the interval should not exceed that over wh
may be expected to persist without material change in thickness, charact
tenor. Closer spacing than the level interval is not justified; max distanc
to 500 ft or more (see Modderfontein B mine, above); it is a matter of exp
with a given orebody. In connection with method of mining, raises and
provide entrance to stopes; serve for handling ore, waste rock for filling, a
plies; are usually the openings from which stoping starts. For these pu
their location varies greatly (see individual mining methods). In veins wh
occurrence is regular, the output required, combined with distance to which
opment has been carried in advance of stoping, sometimes determines th
interval. Each stope has a limited tonnage possibility; the number of
that can be opened simultaneously depends on available points of attac
general extent of development.

West Australian practice. E. D. Cleland states: Where development is consi
in advance of ore requirements, the winzes (or raises) in lowest level may be 500 t
apart, and are sunk merely as a guide to future stoping. In upper levels where

or winze interval must be 125 to 150 ft. This
ccurrence; where ore is irregular, no figures can

inimum clearance between cars on double-
s are always desirable, especially for high

STANFORD LIBRARIES

speed and heavy cars. Shovelers need a total width of about 7 ft to both sides of a small car at face of a drift. (*c*) DRAINAGE DITCHES for large amounts of water may increase width of drift or crosscut beyond quired by car (Sec 6, Fig 12, 13). (*d*) Requirements for VENTILATION may determine minimum size of opening. Design of cross-sec must room for ventilating pipes, if used (Sec 6, Fig 11). (*e*) In veins up to 8 wide, drifts in oreshoots are often carried full width of vein, thus reduc per ton of ore obtained. (*f*) HEIGHT OF DRIFTS and crosscuts is a matter room; 6.5 ft clear is about the minimum.

Drifting and crosscutting by hand drilling is done in connecti exploratory work (Art 13) in small mines, where expense for plant is n fied, and in districts where skilled labor is not available for running drills. Drill holes are not spaced systematically, but placed to take ad of all irregularities in the face. Drilling is done double-hand in hard gro single-hand in aver ground; hand auger is cheapest and best for soft containing few hard streaks, and in coal.

In small drifts, 7 to 12 holes, 2 to 2.5 ft deep, are necessary to advance face 1. These figures vary widely with hardness and toughness of rock; in aver ground an of 0.7 to 1 ft per shift in a 1-man drift or crosscut is good work.

Examples. At BODIE, Cal, 1 miner drilling single-hand in 5 by 7-ft drifts and c width of veins 3 to 30 in, vein rock varying from hard banded to soft granula country rock firm, fairly hard andesite, advances 1.304 ft in drifts and 1.187 ft in per 8-hr shift (84). At RHYOLITE, Nev, 1 miner drilling single-hand in drifts 4.5 7 ft, in fairly soft mineralized porphyry, makes 0.5 to 3 ft per 8-hr shift, aver 1 laying, mucking, and tramming was done by other men). Table 14 is record of driven by hand in ARIZ (1913); cross-sec, 5 by 7 ft; length, 374.5 ft; aver tram 875 ft; rock, fairly soft porphyry; no timbering required; 3-shift contract work by labor, 1 miner and 1 helper on each shift doing drilling, blasting, mucking, and tr Tunnel was completed in 500 man-shifts in 91 days. Aver advance per man-shift varying from 0.359 to 0.852 ft; aver progress per day, 4.12 ft; aver wages per man-shi

Machine drilling, definitions. All types of rock drill are used for drifting cutting. To avoid confusion in this and other articles, terms are used with meaning: PISTON-DRILLS, in which the bit is attached to and reciprocates wi LEYNER DRILL, large hammer-type drill, mounted like a piston-drill. STO (stopers), small drills of the hammer type, with air-feed. MOUNTED STOPE-DR mer drills, mounted by attaching air-feed cylinder to a column or bar. PLUGG small hammer drills (like the Jackhamer), usually having a D-handle, and hel by the driller. (For details of drills, see Sec 15.)

Machine drilling; arrangement of holes. See Sec 6, Art 6.

Location and number of holes depends on several interrelated factors. O small cross-sec afford limited space for drills; length of drill bit then limits a holes in V- and pyramid-cuts and may force use of draw-cut; in some mines wi is increased in hard ground, to allow more efficient arrangement (89). Some drill faster than others in flat holes and uppers, or in certain kinds of ground holes should be planned to suit the drill available. Hard ground requires more soft, especially relievers between cut and squaring-up holes. In soft talcose tings may pack around the bit in wet holes, while dry holes give no trouble; then designed with as few down holes as possible. In general, more economica sults if total footage of hole required for a round is not greater than can be d shift, allowing time for blasting.

Rounds for PISTON and LEYNER drills are shown in Fig 104 to 108 (with Fig 3 to 8, Sec 6). Fig 104 (90) is typical for small arched-back

Fig 104

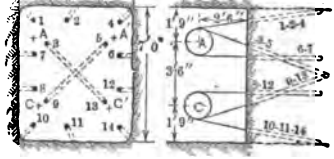

Fig 105. Pyramid Cut

Fig 106.

in soft ground; one more lifter is sometimes necessary. Fig 105 (91) is MID-CUT for small openings in hard ground. The drill is mounted on a column set up in middle of drift; the arm occupies successively positions *A*, *A'*, *C*, and *C'*; in each position, some holes are drilled from top and some from underneath the arm. In soft ground, holes 2 and 11 may sometimes be omitted. Leyner drill is well adapted for this round. Fig 106 (92) shows a DRAW-CUT made by piston drills in aver ground at Cripple Creek, Colo; size of drifts, 3.5 by 6.5 ft to 5 by 8 ft. Fig 107 shows V-CUT in a wider drift, at Homestake mine, So Dak. In drifting along a vein wall, or some other well defined plane of weakness, the SIDE-CUT (Fig 108) is advantageous; it is drilled from a single set-up of a column. Numbers of holes indicate order of firing.

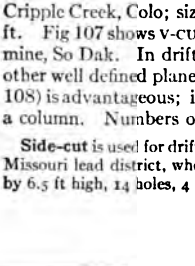

Fig 107. V-cut

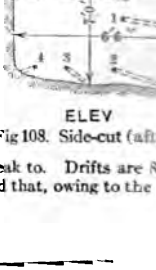

Fig 108. Side-cut (aft

Side-cut is used for drifting in flat-dipping dolomite in S E Missouri lead district, where there is no slip on one side to break to. Drifts are 8 by 6.5 ft high, 14 holes, 4 to 8 ft, making a round. It is stated that, owing to the

d consequently drill and break better (93) (Table

STANFORD LIBRARIES

cost of 27% with small drill. Rate of advance with small drill was 10 to 20% with large drill (96) (Table 16, Examples 10, 11).

Mich copper mines in 1912 introduced 1-man drills and effected marked ec

Alaska-Treadwell mine. Water Leyner 1-man drills have replaced 3-25- drills. The small drill consumes 20% less air per min, but runs more steadily, so air consumption is about same as before. Saving in labor far more than offsets cost for hollow steel, drill sharpening, etc. 4 small drills on a cross-bar replaced 2 l in a crosscut 12 ft wide, with no increase in labor but greatly increased speed of adv For comparison of Leyner and piston-drills for horiz openings, see Sec 6, Art 2.

Mounted stope-drills may be used for drifting, for rounds like those drills. Mounting causes delays in setting up and shifting, but the light advantages (see following data from FRANKLIN FURNACE, N J).

Substitution in drifts of mounted stopers for large piston drills reduced dril from 18.4 to 5.7 man-hr per ft of advance and cost of explosive from $1.84 to $1. latter reduction is due to smaller diam of holes drilled and to flexibility and ease stopers which permit and encourage more efficient placing of holes. Cost for explosives was reduced from $5.33 to $2.70 per ft (98).

Use of stopers and pluggers for drifting and crosscutting was develop West largely by leasers, because of their lower initial and operating costs remarkably low costs have been obtained with them, and they bid fai place other machines in many places, especially in ground which drills an easily. Objection to drifting with stopers is that the muck must be 5 or 6 ft back from face before drilling can begin, also in dry ground t duce much dust unless sprays or water jets are used. For very soft grou ger drills, with automatic rotating device and auger bits, give excellent (See Colby mine, under Cost of drifting and crosscutting.)

Breaking ground in drifts and crosscuts. Data in Tables 16 and in a general way the effect of character of ground and size of cross-sec on and arrangement of holes, kind of drill used, and powder consumption. alizations are difficult, because of interdependent factors; the data indica bilities warranting careful experiment and analysis in planning rounds f openings. With piston and Leyner drills an aver of 1 hole is used per 4 face (= aver burden per hole of 2 to 3 ft). Examples 17 and 18, Table extremes in stope-drill practice in this respect.

Mucking and tramming. Speed of drifting and crosscutting is o termined by time required for mucking, rather than for drilling and If more than one heading is available and speed not essential, it is usually to alternate drilling and mucking crews at any one face, thus giving clean drift in which to set up, and allowing use of full shift for drilling. especially important if drilling is difficult, or if a large footage is requ round. General points in regard to mucking in tunnels (Sec 6, Art 13. apply here also, especially where speed is desired. Table 18, by R. K. gives mucking and tramming duty. A plat of sheet iron or plank, laid close to the face before blasting, materially increases output per mucker-hr on loading and tramming from chutes are included for comparison and f estimating on raises (Art 22; Sec 11, Art 9). Rate of mucking is also aff size of pieces; observations by author in Colo gave following data:

Car, 28 by 28 by 54 in; capacity, 2 500 lb; 1 man mucking small material floor filled car at rate of 3 tons per hr; with good floor, 5 to 6 tons per hr. I muck containing many big pieces, which had to be lifted into the car, 1 man load per hr; 2 men loading mixed material from rough floor and taking their time ha tons per man-hr. 2 men, 1 picking and 1 shoveling, made following rates per m large and small material mixed, 2.9 tons; all big pieces, 3.2 tons; all fine muck, 3.

Timbering in crosscuts is similar to that for tunnels (Sec 6, Art 17) generally lighter on account of smaller cross-sec and shorter life of these op This may be true also of drifts, but timbering in the latter is often desi support filling or ore in the stope (Art 36–38). Usual forms of drift tim

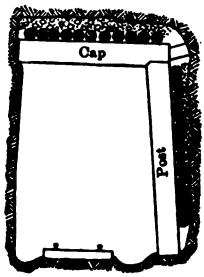

Fig 112. Half Set

(*a*) HALF SET (Fig 112), cap resting in a hitch end and on a post at the other; used where ba one side of drift require support; (*b*) THREE-Q SET (Fig 115, *A*) cap and 2 posts, used where ba both sides require support; is the commonest FULL SET (4-piece), made by adding a sill to th quarter set, is used where the floor is soft (Sec 6, Posts of sets usually have a batter of 1.5 to 2.5 ft of vertical height; increased where lateral p is heavy and sets must be maintained for a consi time (Fig 113). Round or sawed timber is u drift sets (for comparison, see Art 50; also Sec 16). SIZE OF TIMBERS. Round timber is usual 12 in diam; for heavy ground and large openings 24 in diam or more. Ordinarily, lightest sawed used is 6 by 6 in; sizes to 12 by 12 in are common. SPACING OF SETS d on size of timbers, weight of ground, and length to which available laggi cut without waste; usual interval is 4 to 6 ft; in heavier ground, 2 to 3 ft; treme cases, sets are placed skin to skin. LAGGING (*L*, Fig 113), used to prevent falls of ground between sets, is of round 4 to 6-in poles, half-round mill slabs, or 2 to 4-in plank. Plank is used where tight joints are necessary, and in districts where all timber is imported and plank is as cheap as other forms. Length of lagging usually = distance *c* to *c* of sets; it may cover only back of sets, or back and one or both sides; in rare cases sills are lagged also. La on back is usually placed skin to skin; on sides open lagging (Fig 113) is gen sufficient. Space between lagging and is best packed with broken rock. S (stretchers) (Fig 113, *S*) are dis pieces to brace the sets longitudinally; are heavy lagging poles, or 4 by 6 or 6-in timber, cut to fit between sets at between cap and post, and spiked in in shifting ground, feet of posts are b also. Sets are firmly blocked to blocking and lagging often form ade lateral bracing. JOINTS. Simple are desirable; object is to get full str of timbers with as little framing as pos

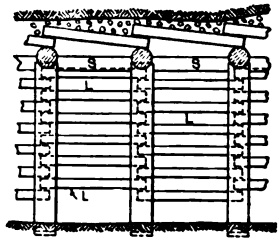

Fig 113

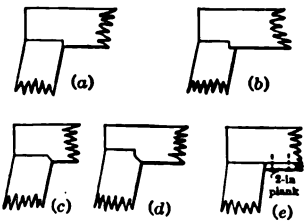

Fig 114. Joints Between Cap and Post

Fig 114 shows typical joints: (*a*) is cheapest to frame, but cap may split u vertical pressure; (*b*) avoids this danger; (*c*) is as good as (*b*) and cheap frame; (*d*) and (*e*) are designed to give both cap and post the strength o

charging. At beginning of shift, muck is cleaned off platform at top, and back down; planks are laid across chute from next to top stull, to prevent steel or t falling into chute; sometimes canvas is spread over these planks to make them long planks are then laid across top stulls extending over the chute; they are stulls at manway end, and, for safety, their ends should be wired down; an open between planks on manway side, through which miners can climb. One ma does this work in about 1.5 hr. The round is then drilled from top platform, in 2 to 2.5 hr; rest of shift is spent in cutting hitches, putting in stulls, lagging, ladders and air pipe. Before blasting, top stulls over manway are covered wi plank and blocks (Fig 120). Sometimes pockets are cut (*P*, Fig 120) at interval 40 ft, in which to store drill, tools, etc. One man doing all the work has raised month (this is above aver speed. Author). In a 1-man raise of this kind, depth and consequent advance per round is adjusted so there will be time to keep the t up. It is usually best to blast on each shift; hence, holes are limited to from 2 to

Fig 121 shows method of driving a small inclined raise (113). Up to dip of 4 ber is required to support men; at angles above 30°, it is best to place small hor or 5 ft apart and 6 to 10 in above footwall. Muck collects behind these and fo which aid in climbing raise and supporting drills; the steps also catch steel a dropped accidentally. Support for tail-piece of stope drill may be obtained fro brace, as in Fig 121. (At Braden Copper mine, Chile, 2 short pieces of drill ste into plug holes drilled in footwall, carry a plank placed on edge across the raise, turn gives footing for drill. No back holes are required, as the ground break Christensen gives following data for aver conditions in a 1-man raise: "To clean get ready to drill need not take over 1 hr; to put in round of 8 holes, averaging takes 1.5 to 2 hr; if a nipper brings powder to miner, it is possible to shoot tw making 4 ft per shift; otherwise, max daily aver advance expected is 2.5 ft." raises on dips of less than 35° to 40° require shoveling (Table 22, Ex 5).

Several raises connecting levels for ventila-
distance 113 ft; cross-sec of raise 6 by 8 ft.
level below. Dry ore with considerable fines
up and block chute; at 34°, large pieces jump
slope of 34° for first 10 ft, flattening gradually
ope drills; 6 to 9 holes per round, loaded with
2.5 ft. Distribution of cost per ft: labor,
96; labor, loading cars and tramming, $0.93;
blacksmith, $0.24; explosives, $0.80; chutes,

Round Mountain Mining Co, Nev. R. H. Ernest, Supt, furnishes foll for aver conditions in 1916: cross-sec, 5 by 8 ft; rock, medium hard, tight Ingersoll-Rand CC-11 stope drill; 12 5-ft holes per round; 22 lb 40% gelatin per round; advance, 4 ft per round, with 1 drill shift of 1 driller and 1 muck

Melones Mining Co, Melones, Cal. J. A. Fulton, Supt, furnishes followi 1916. Raises 6 by 7 ft; ground, amphibolite schist containing irregular quart medium hard, fitchery, but breaks well; on the footwall is a banded quartz v difficult drilling; Ingersoll-Rand BC-21 Butterfly stope drill; 14 holes (= 80 per round, giving 3.25 ft advance with 2 drill shifts; 51.5 lb of 40% dynamite crew, 2 drillers. A winze, 7 by 11 ft, is kept 2 levels ahead of shaft, crosscuts the shaft raised from them. Shaft sinking costs about $46 per ft for break and timbering. Raising and subsequent stripping down to full cross-sectio costs about $36 per ft for same items. In the winze, ground is like that in holes are drilled in footwall quartz vein, giving more trouble than all of the r hamer and 1-man piston drills had a thorough trial in winze, but difficult gro use of 2-man, 3-in piston drill. In the winze, 24 holes (154 ft) are drilled per r advance per round, 5 drill shifts, 4.5 ft; 120 lb of 40% dynamite used per rou per round, 4 drillers, 4 helpers, 3 muckers.

Raising through an old filled stope at Silver Plume, Colo (Fig 122). One was next to solid rock, but same plan was used where raise was entirely surround material. Filling was well packed, and would not run in large amounts. Orig to 4 ft wide; walls, fairly strong. Timbering consists of 3 rows of short stulls apart, set in hitches, and dividing raise into a manway and chute. 2-in plan to middle row of stulls, to form a tight partition between compartments. Pl used for lagging the outside spreaders. Only half the face of the raise is advan time, topmost stulls on other side being covered with planks to form a roof for of miner when at work. Excavation is done with a bar, loose material falling below. When face has been advanced about 2 ft, temporary stulls *a* are put

Standard Consol mine, Bodie, Cal, 1905. Hand drilling; miners, $4 per 8-h
Cost per ft: drifts, $4.38; crosscuts, $5.15; raises, $3.65; shallow winzes, $5.55 to
aver cost all development, $3.92 per ft, of which labor was $2.80 and supplies $1.1

Mining companies often publish footage costs of development work w
segregation into costs of drifts, raises, crosscuts, and winzes; these are use
preliminary estimates in same districts. Following costs per ft are mostly
from company reports.

Mary Murphy Gold Mining Co, Cripple Creek, Colo, 1915. 4 401 ft drifts;
ft crosscuts; 1 677 ft raises; aver cost, $7.22.

Elkton Consol, Cripple Creek, Colo, 1915. 2 939 ft drifts, $3.98; 175 ft raises,
207 ft winzes, $9.55. Costs cover labor and powder only. Contract prices for dri
$6, and $6.50; for winzes, $11.50.

Portland Gold Mining Co, Cripple Creek, Colo, 1914; drifts, $6.62; crosscuts,
raises and winzes, $7.77.

Liberty Bell mine, Telluride, Colo, 1911. Contract price for drifts 6 ft wide b
$8; for widths exceeding 9 ft, $11; 3.25-in piston drills; contractors buy powder, fuse
and candles from company, place stulls and lagging, and tram muck not over 500 ft

Nevada Hills, Fairview, Nev, 1914. Drifts and crosscuts, $8.15; raises,
winzes, $15.27; total footage of all kinds, 5 697 ft.

Nevada Wonder, Wonder, Nev, 1914. 11 276 ft drifts, crosscuts and raises
cost, $6.44.

Montana Tonopah Co, Nev, 1910. Drifts, $6.24; crosscuts, $5.84; raises, $5.1

West End Consol Mining Co, Tonopah, Nev, 1913. 1 546 ft drifts, $6.50;
ft crosscut, $6.44; 1 512 ft raises, $6.66; 383 ft winzes, $13.39.

Silver King Consol, Park City, Utah, 1915. Development and exploratory drifts,

Consol Mercur Co, Mercur, Utah, 1912. Aver cost 3 657 ft develop't openings.

Wolverine Copper Co, Mich, 1912. 4 293 ft drifts, $6.12.

Franklin Mining Co, Mich, 1912. 4 365 ft drifts, $5.79; 199 ft crosscuts, $5.57
ft raises, $9.30.

Mass Consol Copper Co, Mich, 1908. 6 410 ft drifts, $5.75; 466 ft crosscuts,

Alaska United, Douglas Island, Alaska, 1913. Ready Bullion mine, 3 997 ft dev
ment, $13.40; on 700-ft claim, 2 783 ft, $11.92.

Alaska Mexican, Douglas Island, Alaska, 1913. 2 464 ft development, $15.75.

Alaska-Treadwell, Douglas Island, Alaska, 1913. 5 980 ft development, $13.80

Le Roi No 2, Rossland, B C, 1913. 3 503 ft drifts, 628 ft crosscuts, 482 ft raise
ft winzes, total 4 633 ft; aver cost per ft, $15.87.

Hudson Bay mine, Porcupine, Ont, 1913. 298 ft drifts, $14.43; 446 ft crosscuts, $1

Kerr Lake Mining Co, Cobalt, Ont, 1913. 2 974 ft drifts, 1 663 ft crosscuts, 16
raises, 186 ft sinking; total 4 984 ft; aver cost per ft, $5.84.

ITATION

eneral

the means of supporting the COUNTRY ore itself, during the process of stoping. y or temporary support. In some cases, n or slabs of rock or ore; in others, large part of the method.

ing methods are: (*a*) Surface and over- PILLARS left in the orebody; chambers s, the removal of the ore being incom- the orebody and filled either contem- ste (as broken rock, sand or gravel). the pillars are mined; filling, if contem- and stope walls during mining. (*c*) A nd overlying material allowed or forced adjacent sections. Or, successive por- d then broken down by weight of the their own weight. CAVING METHODS above the deposit.

aried in many ways. In veins or masses, usually mined in descending order; to ated on as few levels as possible; num- ly depends on the size of deposit, distri- d. In large, uniform deposits, the ideal hat above is being mined, and at same w. Relative times required for these 3 orebody, determine sequence and extent ning. Development on a level is often rted on that level. In flat beds, mining simultaneously, the workings being ex- oint of entry; such methods are called TREATING SYSTEMS, development open- ndaries, where mining begins, the work- int of entry. These terms apply also,

varying importance. The method chosen t and extraction. Last 2 factors are closely of the orebody often yields maximum total so planned that low-grade ore and pillars, future if desired. Improvements in mining o lower the tenor of profitable ores.

STANFORD LIBRARIES

Classification of underground metal-mining methods. A logical c
tion, based on the factors outlined above, is impossible, because of their
relations. TYPE OF STOPE is used here as a basis of classification; the stop
selves are grouped, according to modes of supporting walls and men, as

I. Open Stopes..... (Art 29 to 44) IV. Shrinkage Stopes.. (Art 6
II. Timbered Stopes.. (Art 45 to 58) V. Caving Methods.. (Art 7
III. Filled Stopes..... (Art 59 to 67) VI. Combined Methods (Art 8

This arbitrary classification is adopted for presenting the details with a mir
duplication. For classification of metal-mining methods from standpoint of th
cability to different types of orebody, under different conditions as to charact
and wall rocks, see Art 94.

26. Breaking Ground in Stopes.

Breaking ground covers the work of blasting, including locating,
charging, tamping and firing drill holes. For charging and firing, and
explosive for different kinds of work, see Sec 4 and 5.

Fig 123 shows a drill hole AB in vertical section; top A and bottom B of a
called its COLLAR and TOE. Holes pointing downward are DO
or WATER HOLES, water being usually kept in them while drilli
holes, or those at a slight angle above or below, are FLAT HO
Fig 126); holes drilled steeply upward are UPPERS (UP, Fig
holes which will not hold water, and uppers, are also called DR
In Fig 123, the rock surfaces CD and DG are FREE FACES, a
the LINE OF LEAST RESISTANCE of hole AB. Length of lin
right angles to AB, is the BURDEN on the toe of the hole. (F
data on blasting, and remarks on Theory of blasting, see Sec
6, 7.) In practice, the arrangement of holes and weight of c
matters of judgment, based on experience under similar conditions and modified
ment with the rock or ore to be broken.

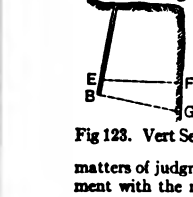

Fig 123. Vert Sec

Breast stoping. Ore is broken by flat or slightly inclined holes, dri
vertical face (or breast) of considerable lateral area, which is being adv
a horiz or nearly horiz direction; work resembles that of advancing th
a very wide drift. This method is used in flat, thin beds; also in parts o
or wide veins, to provide openings for other methods of attack (Art 30

Underhand stoping. Ore is broken in horiz slices, in descendin
miners stand on ore and drill holes downward; for different forms
which result, see Fig 147 to 153, Art 33.

Overhand stoping. Ore is broken in horiz or inclined slices, in a
order; miners work beneath the face of ore; holes may be flat, uppers,
holes. For different forms of overhand stope, see Art 36.

Underhand and overhand methods are employed under widely different con
to size and nature of orebody; in both, the stope faces are usually maintained i
benches (Fig 147, 159, 161). Ore is blasted in blocks from free ends of be
nearly all cases there are at least 2 free faces, to which a hole can break.

Caving (Art 71). A portion of the orebody is undercut and allowe
by its own weight.

Objects sought in breaking ground are: (*a*) to break ore from sto
(*b*) to break ore into pieces of a size suitable for handling.

Very large pieces of ore clog chutes and mill-holes and can not be handle
they must often be broken in stopes by sledging or BLOCKHOLING (Sec 5, Art 7).
require large amounts of explosive (see note m, Ex 8, Table 29). Shallow ho
spacing of holes, and high grades of dynamite, all produce fine breaking, but a
cost. Th[illegible] usually easily adjusted in narrow stopes; in wide dep

ease depth and spacing of holes and to block-
127). Economy of this practice depends on
ower; the manner only has greatly cheapened
n stopes to a smaller size than necessary for

STANFORD LIBRARIES

Ordinary limit of depth of hole drilled by 3 to 3.25-in piston drills, 16 to 20 use of deep holes in a large stope, see Ex 15, Table 30. Deep holes make for breaking; objections to them are: (*a*) long steels are awkward to handle under (*b*) ore may break in large pieces difficult to handle along stope face. Objection not be serious; deep holes usually make steep faces, where large pieces come to rest at foot of conveniently for blockholing. Usual depth of drill holes in wide underhand stopes is less than economic limit of depth of hammer-drill holes, to 8 ft. Burden broken with holes placed as in depends largely on character of ore and must be mined by experiment. In easy ground, max d between holes and between rows of holes is 0.75 depth of hole (Art 26). In tight ground, at Alaska-Treadwell, 12-ft holes were dril apart in rows 2.5 ft apart, and staggered as in Fig 125 (133). For further de spacing and depth of holes, see Breast stoping, Art 30.

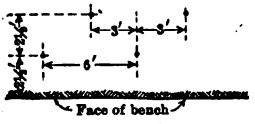

Fig 125. Plan

Overhand stoping comprises STEPPED-FACE and FLAT-BACK STOPE also Art 36). Fig 126 shows part of a stope face. Benches may be brol flat (breast) holes, running across stope, as at *FT*, or by uppers, *UP*. Uppers are often pointed as at *IC*, so that cuttings will fall clear of drill. In narrow veins, uppers are drilled parallel to dip to avoid breaking into walls.

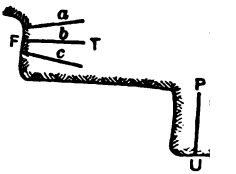

Fig 126. (In wide stopes, a vert, longit sec; in veins, a sec in plane of

Uppers *vs* breast holes. Uppers are well adapted to efficient use of stope-drills, but they shatter, more than breast holes, the back under which men must work in drilling the next slice. This is more important in wide than in narrow stopes, especially in presence of horiz slips. Breast holes can often be drilled as water holes, thus avoiding nuisance and danger of dust.

At Baltic mine, Mich, and in parts of Portland mine, Cripple Creek, Colo., holes are said to break ground more efficiently than uppers, besides being saf Broken Hill, N S W, in mining wide lodes in flat-back stopes, uppers are prohib a safety precaution (141, 142). Breast holes may or may not be harder to dri uppers, depending on character of ore.

J. A. Fulton, Sup't Melones mine, Cal, furnishes following data showing that ch of ore may influence in other ways the choice between breast and upper holes, filling at Melones is amphibolite schist, with irregular quartz stringers. Vertic are parallel to schistosity and will not break ground in wide stopes; when blaste leave long jagged pieces projecting from the back, which are dangerous and i impossible for following shift to place and drill their holes advantageously. breast holes across the schistosity is easier, and explosive acts much more effectiv

Uppers are common for overhand work in narrow stopes on steep dips; breas are used in such stopes on low dips. This is true of both hand and machine type of drill used also affects choice (see below under Choice of drills for stoping). may be drilled with either piston or stope-drills, usually the latter; breast hole piston-drills, which, in stopes up to 8 or 10 ft wide, are mounted on bars; in wider usual mounting is a column braced between back of stope and filling or timber.

Height of bench in machine-driven, overhand stopes depends on same as for underhand work. In narrow stopes, benches are 3 to 6 ft high; i stopes, breast-hole benches are 6 to 12 ft high, broken by 2 to 3 rows of 6 or 14-ft holes (*a*, *b*, *c*, Fig 126). Benches broken by uppers are usually 5 high and holes have corresponding depths. Tables 29 to 31 show prac to depth of hole. In square-set stopes (Art 46), depth of either breast or holes is determined by dimensions of sets (note *k*, Ex 16, Table 30).

Character of ore may influence depth of hole, and therefore height of bench; at Consol mine, Nev, 5 to 7-ft holes are drilled in very soft ore, because blasting chambers the bottoms of deeper holes, failing to break (143). Usual range of

STANFORD LIBRARIES

operated augers, or plugger-drills with an automatic rotating device so tha can be used as either augers or pluggers, are the logical choice.

Many of the remarks on choice of drills for drifting (Art 21) apply here. Fo holes in underhand stoping, hammer drills are efficient. In steep-dipping overhand where the holes are uppers, stope-drills are best under aver conditions. They are li allow holes to be pointed as desired; delay in setting up, incident to piston-drill avoided and that due to changing steel is reduced. But, hammer drills produce mu unless used with a water jet, and are not suited to very hard ore; in the latter, pist are used for uppers, choice between 1 or 2-man sizes depending on difficulty of dri

Breaking ground with uppers in overhand stopes on flat dips (20° to 30°) re breast stoping; character of ore then determines whether stope or piston-drills used; in some dry ores, cuttings will run out of holes drilled on angles as low a 20° above horizontal; in moist or clayey ores, cuttings may pack around stope-d even in vertical up holes; all conditions are found between these extremes. E differ as to choice of proper drill for narrow, flat-dipping deposits. Modern shows an increasing use of stope and plugger-drills. In general, piston-drills a (*a*) in ground that is very hard or that fitchers badly, even if soft (Leyner dri times overcomes the latter condition); (*b*) in large-scale blasting with deep large stopes. MINIMUM WIDTH OF STOPE in which piston-drills operate effici about 4.5 ft; this width is apt to be exceeded, especially for large drills. St plugger-drills can be used in stopes about 3 ft wide on steep dips, but require c supervision to maintain this minimum. Minimum possible width of stope is increased by flat dips. In narrow orebodies, where clean mining is desired, these influence choice of drill and also choice between hand and machine drilling (Art

Examples illustrating foregoing discussion. LIBERTY BELL MINE, Tellurid (131). Quartz vein, aver stoping width 4.3 ft and aver dip 57°, was formerly m hand drilling, as vein matter was crushed and loose, and economy of air drills narrow veins was doubted. Table 27 shows effect on breaking costs produced by

from dominant hand mining in 1906 to machine mining in 1910. Stope-drills a for mining overhand by uppers; a saving of 54.5% in stoping labor result change, notwithstanding that drillers were paid more than hand miners. BERLI Nev. Hard quartz vein, aver width 2.6 ft, aver dip 40°, was mined clean and at by single-hand drilling in overhand stopes (Berlin mine, Art 27). An attempt to hand-drilling with 2.75-in piston-drills failed; stoping width with machines i to about 5 ft; mill had a fixed capacity and no sorting was done ahead of it; material sent to mill was lowered about 50% and tonnage increased but little; o resulted in a loss. FRANKLIN FURNACE, N J. Overhand stoping; ground h sistency of hard, tough limestone and is now broken by uppers drilled with sto in large stopes. B. F. Tillson gives data in Table 28, showing effect of changi all 3-in piston-drills in 1908 to all stope-drills in 1913; extensive tests on numero were made (98). MELONES MINE, Cal. J. A. Fulton, Sup't, furnishes followi (see also Ex 4 to 7, Table 30). Ore is schistose, containing quartz stringers. A 3-in piston-drill put in 8 6-ft holes per 8-hr; 1 man, with a Sullivan Liteweight piston machine, drills 7 6-ft holes in 8 hr. The 1-man drill is therefore chea 3-in drills are used in one orebody, where ore is mostly quartz, and for holes in quartz vein on the footwall of some stopes. (See Overhand stoping, Art 28, fo tions of stope-drill for uppers in this ground.) ALASKA-TREADWELL MINES Kennedy gives following data in 1916 (97); for method of mining, see Art 69. mineralized diorite (Ex 8, Table 29). For years, 3 to 3.25-in piston drills were

STANFORD LIBRARIES

Type of orebody to which breast stoping is applicable is indica
the following description of Missouri lead and zinc deposits, in which the
has been extensively developed.

S E Missouri. Disseminated galena ores occur as flat or slightly incline
dips 3° to 10°) tabular masses in dolomitic limestone; thickness of deposits, o t
depth, 200 to 600 ft; aver tenor of ore for district, about 5% lead. These depo
irregular in horiz outline and cover considerable areas (Fig 130). Limestone
generally good, with local shaly and fissured areas. JOPLIN, S W MISSOURI.
stoping is used exclusively for mining flat or nearly flat bedded deposits of spha
chert, locally called "sheet ground"; depth of deposits, 75 to 250 ft, aver 175 ft
ness of beds varies from a pinch to over 20 ft; aver thickness of workable depos
10 ft. Overlying rock is strong limestone; in some cases, ore is overlain by 2 t
hard flint, which stands well and makes a clean roof to break to. Ore is lo
averaging a little less than 2% zinc. Methods of exploring these deposits are
Art 11. See also Wisconsin zinc deposits, below, and Mineville, N Y, Art 31.

Development. A vertical shaft is sunk to bottom of orebody; pra
no lateral development precedes mining; preliminary boring outlines the o
in a general way; stopes follow the ore outwar
shaft (Fig 130).

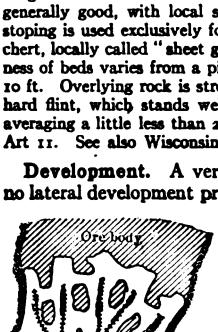

Fig 129. Plan of Breast Stope

General plan of work. Fig 129 shows

different stages of work; obviously, the face
advanced in any direction. Fig 130 is a plan
of a mine in S E Mo, showing application of
over a large area (55).

Breaking ground. Methods vary locally and with thickness of or
as illustrated below (see also Ex 16 and 17, Sec 21).

S E Missouri. H. A. Guess gives following data (55). Where ore is less than 8 ft thick, face is advanced by breast holes; drills are mounted on columns; where there are well-marked bedding planes on top and bottom of ore, 2 holes in a vertical plane suffice, otherwise 3 holes are required; top and bottom holes are in same vertical plane, center hole is set 6 in nearer the face to be broken. All holes are approx parallel to face to be broken (compare with Fig 132). The 2 lower holes slope enough to carry water, top hole points a little upward. Aver depth of holes, 7 to 7.5 ft; in starting a stope or in turning around a pillar, face is broken into by 3 cut holes 4 to 6 ft deep. Where ground is carried with 2 holes, burden is usually 3 ft; with 3 holes, burden on middle hole is 3.5 ft, on others, 4 ft. In thicker orebod upper part is mined by breast holes as above; lower portion, called the stope, is

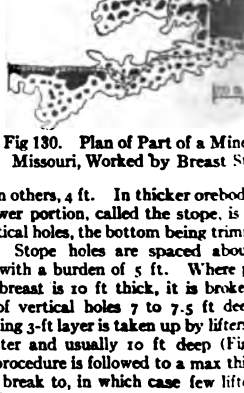

Fig 130. Plan of Part of a Min

Wisconsin zinc district. Deposits of ZnS and PbS occur in pitches and fl limestone; some are so irregular that mining is practically gophering; larger de are commonly mined by breast stoping. Orebodies are from 5 to 70 ft high, 20 t ft wide, and 500 to 7 000 ft long; roof is generally solid, thick-bedded limestone; de lie at depths of 75 to 200 ft. George (162) gives following d breaking ground: Fig 135 shows method; in headings 6 to 7 ft 8 to 10-ft holes are drilled from umn; heading is kept 15 to 2 advance of benches, which are 10 ft high; bench or stope hol 10, 12, or 14 ft deep; both p and plugger-drills are used. Ac ing to character of ground, a mac man drills 50 to 100 ft of hole per shift in headings, and 30 to 60 ft in stope work headings, at least 1 ton of ore should be broken per ft of hole; in stopes, up to 1 per ft; aver varies from 1.5 to 5 tons, depending on height and width of stope and ence of openings at the top " flat " of ore in the heading. Fig 136 shows plan of hea

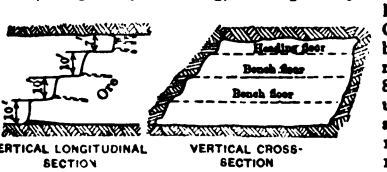

Fig 135

holes 1, 2, 3, 4, which break out hatched areas; C, C', C''. Fig 137 is a cross-sec of an irregular ked out as a breast stope, g mining on 2 levels. In bench are worked simul- ing connected by an in- A, or in rock at right of narrow orebody, the roof over entire width; for would be left (Fig 129).

for light pressures and in strong, low-grade ore. Where roof is fissured wi joints or cracks, stoping may unkey large slabs; this danger is partiall by a systematic staggered arrangement o

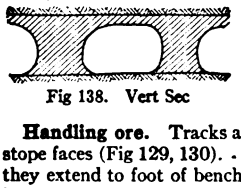

Fig 138. Vert Sec

In some S E Mo mines, ore occurs in ov beds, separated by barren limestone. worked from separate levels, care being t the pillars in upper and lower beds shall b over each other.

Handling ore. Tracks are laid on floor of deposit, from point of en stope faces (Fig 129, 130). In thin deposits, tracks run into headings; they extend to foot of benches. Where more than 1 bench is worked, ing ore is shoveled to foot of lowest bench; general slope of benches is to minimize handling. Broken ore is shoveled into cars, and tramme by hand, or by animal or mechanical haulage, depending on distance an in small mines, buckets are mounted on light trucks, reducing cost o and hoisting equipment. Air hoists are used to haul cars up ste caused by local rolls in footwall.

At some Joplin mines, shoveling plats of 2 by 12-in oak plank are laid at foot over 16 ft high. Attempts have been made to use steam shovels of Thew t ated by compressed air or electricity, for loading into cars (160). For use Whalley machine at Flat River, Mo, see Art 92. H. A. Guess (55) states th men shoveling from rock floor into 1-ton cars averages 18 tons per man-day i Long handle, round point, No 2 shovels are used; a 1-ton car takes 130 sh 15 lb per shovel; aver cost of loading in 1914, 13¢ per ton. Records for Jop on contract work vary from 18 to 22 tons per man per 8 hr, shoveled into buc tract prices for 1913, 4 to 8¢ per bucket of 800 to 950 lb (111). Contract prices work in Wis zinc district in 1915 were 5 to 7¢ per bucket of 1 000 lb (162). See

Percentage of ore left in pillars depends on following factors: (*a*) CH OF ROOF determines max allowable width of heading which will stan ported, and therefore the distance between pillars; (*b*) CHARACTER O a soft floor requires pillars of large area, or closely spaced, so that thei power will not be exceeded; (*c*) STRENGTH OF ORE determines minimu of pillar to withstand pressure of overlying rock; (*d*) DEPTH OF DEPOS mines total wt to be carried on pillars, where deposit has such later that the overlying rocks do not arch, and become self supporting (see Su Art 115). These factors are interrelated; their effect cannot be defi termined in advance in new districts; it is obvious that the percentage in pillars may be fairly constant in a given district, but vary widely in localities. Table 33 gives percentage losses in pillars, representing e of different engineers in Missouri lead and zinc districts.

Recovery of ore from pillars in a systematic way is rarely attem mining method like breast stoping is justified by its simplicity and and because, where properly applied, it yields a max profit in spite of of pillar ore. Use of method should be confined to low-grade deposit value of ore in pillars will not repay cost of replacing them by artificial

At Joplin, in some mines leasers clean up floors and pillars in worked-out area is not systematic; as pillars are trimmed as far as men dare, several disastr have occurred. Attempts have been made to take out pillars, starting at b and retreating toward shaft; such work is costly and dangerous; the caving of r results may destroy the remaining pillars and may extend over large areas. deposits, where ore is soft and weak, stopes are small and pillars contain as 50% of orebody; attempts to mine the ore in pillars have resulted in loss or v profit. Following methods have been tried in these mines for pillar recovery: timber cribs were built in stopes around pillars, to support roof while pillars w mined; timbers failed, much ore removed was mixed with waste and much

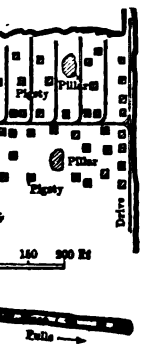
rried parallel to either dip or strike; in
s called DIP WORKINGS; as dip increases,
becomes the same as that in underhand
ethod is limited to deposits with strong

frica. W. L. Honnold gives following
of 7°, is broken by dikes and faults;
; both reef and hanging wall are harder
at cohesion and tenacity. Ore is in large
irregular shoots, gen-
erally elongated along
dip; one measures 700
ft on strike by 4 000 ft
on dip. Stope widths,
57 to 70 in. In 1915,
workings had reached
a vertical depth of
4 100 ft (for character-
istics of Rand banket
see Art 41).



Method of mining (Fig 140). There are 2 vertical shafts, 4 400 ft apart in direction of dip, connected at bottom by an incline on the dip. Levels are 500 to 800 ft apart; varying dips give
inzes connect levels at points near middle of
el to dip; cars are run to face and handled
d timber cribs support the roof.

STANFORD LIBRARIES

Breaking ground. 2.75-in and 3.25-in piston-drills are used, the smaller fo faces under 5 ft high. 1 white man on contract supervises 4 drills, each being 2 Kafirs; 1 drill carrier serves 2 machines. Hammer drills are being introduced fully (1915) for uppers. All holes are drilled wet where possible. Generally, on th much stoping is done by hand. Machines are used at Brakpan because: (a) nati is often scarce, and is inefficient for flat or upper holes, required by the flat dip; is wider than in most Rand mines; hence, the increased stope width inevitat machine drills does not break excessive amounts of waste (see Art 41).. 57% of e used is blasting gelatine (92% Ngl); rest is gelignite (60% Ngl). Large drills t aver of 11 tons per shift; small drills, 7 tons; aver stope widths, 70 in and 5 spectively. Aver stope widths exceed aver reef width by 22 in.

Stoping. Fig 140 shows face of a well opened stope. Work begins at corner block, at both top and bottom of a winze; at first diagonal cuts are taken, giv appearance of overhand stoping (Art 36) at bottom, and underhand stoping (at top, of winze; but when face has advanced 100 ft it is parallel to winze (Fig

Support of roof is by pillars of ore and 10 by 10-ft timber cribs (pigsties) being sometimes filled with rock. Both cribs and pillars are irregularly spac respect to faults and haulageways. The strong quartzite roof settles gradually; faces advance right and left from winze. Eventually pillars are robbed, much crib timber is taken out and the stope allowed to cave. Pack-walls (Fig 170) pro levels, and must be maintained through worked-out areas.

Handling ore. A track is laid in the winze, with a small hoist at top and halfway down. Lateral tracks are run from winze track to the stope face ever Ore from upper half of stope is hoisted to level above, that from lower half is to level below (Fig 140). Winze tracks are shifted toward stope face as roof set requires. Cars hold 1 ton (20.5 cu ft); native muckers receive 8 to 10¢ per car and handle about 6 tons per 8 hr.

Park City, Utah. Fig 141 shows the dip workings of Silver King Coalit J. Humes gives following data (134): silver-lead orebodies occur as replac in limestone; thickness, 1.5 to 25 ft; dip, 10° to 30°; oreshoots are irreg outline and make off from fissures which gave access to mineralizing solu

Method of mining. Exploratory drifts, in the ore-bearing bed, follow the when a drift cuts ore, stopes are started to the dip and carried as far as broken r be shoveled out. If ore co a small hoist is installed. is laid on floor of stope an cars run to stope face. If is thin, enough of footwall out to admit car. If the rary inclines strike barre the tracks are turned and the ore. In orebodies of la eral extent, small drifts (s els) are run to right and le the main incline. Stopin ceeds both up and down di sub-levels, in which run sm

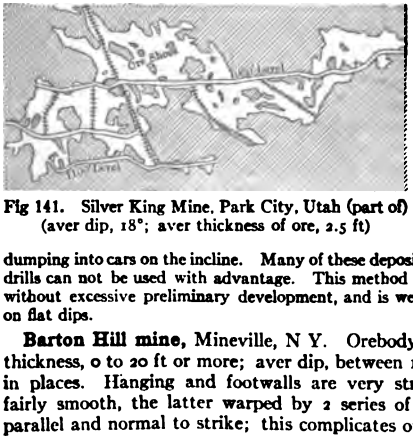


Fig 141. Silver King Mine, Park City, Utah (part of) (aver dip, 18°; aver thickness of ore, 2.5 ft)

dumping into cars on the incline. Many of these deposits are so flat and thin that m drills can not be used with advantage. This method permits mining irregular ore without excessive preliminary development, and is well adapted to handling brok on flat dips.

Barton Hill mine, Mineville, N Y. Orebody is a bed of strong magn thickness, 0 to 20 ft or more; aver dip, between 15° and 25°, rising to 35° in places. Hanging and footwalls are very strong tough gneiss, the f fairly smooth, the latter warped by 2 series of ridges, the axes of whic parallel and normal to strike; this complicates ore handling.

Method of mining. Deposit was first attacked at several points along outc breast stoping to the dip. Mine cars were hoisted to surface on inclined tracks o

s for roof support (note that inclines were swung temporary horiz tracks were also laid to reach

nderground electric hoists. In places, the stope ear incline, to give headroom for dumping into Brakpan mine in that the roof is supported permanently by pillars of ore; irregular footwall makes stope tracks crooked; steeper dips prevent handling stope cars to the level.

Breaking ground. Following data were furnished by the management: holes, 4 to 6 ft deep; in 1912, an aver of 26.58 ft of hole was drilled per shift with 2.75-in piston-drills on tripods; records for 7 mo show aver production of 15.53 tons per drill-shift in stoping and development, and 19.91 tons per drill in stopes alone. In 1913, prizes were offered for best footage drilled per shift. In a 14-weeks' run, 1st, 2nd, and 3rd prize-winners drilled averages of 41.2, 36.36, and 35.14 ft hole per shift; aver of next 12 men after prize-winners, 27.17 ft. Hammer drills, substituted for many large machines, average 40 to 50 ft of hole per shift. 40% dyna-

break the arch pillars into the open stope below, beginning at boundary and toward shaft; in old workings this is apt to be dangerous.

Examples. DUCKTOWN, TENN. Orebodies are large, lenticular masses c phides, carrying 1.5% to 2% copper; aver width, 60 ft; dip, 70° to 80°; ore, tough; country rock is schist; both ore and walls stand well. At Burra B an inclined shaft is sunk in footwall about 100 ft from orebody; level inter at each level a crosscut is driven to orebody and drifts run in each direction; put up from drifts at intervals of 50 ft or less to within 20 or 30 ft of level abo ings are opened from tops of raises, and benches are broken in steps 6 to Details of development vary. On upper levels a raise was made near point w cut entered orebody, and stopes started each way from it (180). Since 1910, t has been replaced by shrinkage and other methods. ARMINIUS MINE, Mineral, tabular mass of pyrite; width, 8 to 60 ft; dip, 60°; the strong slate walls stan no timber was used (181). Level interval is 50 to 100 ft; drifts, 10 ft wide. put through to level above at a 45° angle; heading is opened 12 ft below level worked in 4 to 6-ft steps. A pillar 12 ft thick is left over back of lower level dropping ore to haulage level pierce this pillar at 25-ft intervals. Pillars are necessary, amounting to 33 to 50% of the orebody.

35. Underground Glory-hole Method

General. This method, also known as UNDERGROUND MILLING, is tation of opencut methods of same name (Art 100). The top of a raise i in all directions, making a funnel-shaped opening (GLORY HOLE, or MI which is widened and deepened by underhand stoping. Face of a glo usually carried in benches, forming in plan rough concentric circles around the raise as a center (Fig 156). General slope of face must enough for broken ore to move by gravity to the raise.

Often, before milling begins, sub-levels are run through the orebody to con at vertical intervals of 25 to 50 ft. F. W. Sperr states that, for economical raise interval on each sub-level should not exceed 25 ft. This condition c by inclined raises branching from the main vertical raises. Economic interv raises and sub-levels depends also on hardness of ore. (For full discussion o raise method, see Bib 182.)

Applicability. Method is limited to large orebodies, as masses veins, with strong walls and ore. Back and side walls of a glory hol inaccessible as stoping progresses, with great danger from falling sla but strong ground.

Fayal mine, Minn (183). Hematite, underlying a cover of 65 to 90 ft drift, was formerly mined by underground milling in rooms 24 ft wide, 60 ft hi to 100 ft long. A drift was run under center of proposed room, with raises ore at about 50-ft intervals. A wide drift was then run over top of room an with saddle-back stulls (Art 36) and heavy lagging; under this protection ore into raises. Walls of finished rooms were vertical; pillar widths, 23 ft. Wh was mined out it was filled, intervening pillars being mined by top slicing (Art of timber for supporting backs of glory holes is rarely feasible.

Application of method to inclined deposits is limited to those having dips ste for the footwall to clear itself by gravity. Ore breaking and handling are c benches being carried, with deep holes. Since no sorting is possible in stopes, must be uniform. Following examples show applications to different types o where all or most of ore mined is from glory-hole work. The method is also auxiliary for cheap mining of rooms between pillars mined by other methods, a mine; see also Ohio Copper Co's method (Art 81).

Section 21 mine, Marquette Range, Mich (153, 184). Fig 155, 156 sho of mining a steep-dipping lens of medium hard hematite; footwall, diorite jaspilite. Shaft is in footwall. To open a level a crosscut is driven from foo ing; walls are then followed until drifts connect (see plan, Fig 155); crosscuts between foot and hanging-wall drifts at intervals of 50 to 60 ft. Footwall rais

development has advanced far enough for a with other work on level; other raises are as

over, and a ratio of about ⅛ between angle of
angle of dip on flatter dips (187); usual practi
between these limits. Object of setting stulls wit
is to prevent their falling under weight of ore
to cause them to tighten under small settlement of hanging wall. Foregoing
to placing stulls in both overhand and underhand stopes, as well as to stulls
If footwall is weak, a FALSE STULL may be set underneath main
stull (Fig 164). In steep-dipping or vertical veins with poor
walls, stulls over levels may be reinforced, Fig 165 (186).

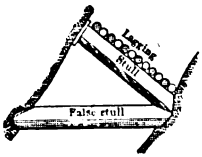

Fig 164. Stull Timbering

Fig 165. St

Maximum economic length of stulls, placed as in Fig 163, varies from 12 to 20 ft, depending on timber supply, facilities and room for handling timber underground, lateral pressure from walls, and relative cost of alternative methods. Usual max width of vein in which single stulls are used to protect levels (also for supporting slabs and men in open stopes) is about 15 ft. SADDLE-BACK STULLS (Fig 166) may be used in veins up to about 25 ft wide. They lack lateral rigidity, and are apt to fail by buckling sidewise; will support vertical wt of broken ore or waste, but do not resist wall pressure; joint at apex must be carefully framed and fitted. They have a limited application, and many engineers obj
under any conditions.

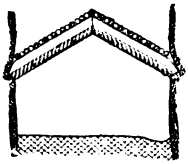

Fig 166. Saddle-back Stull

Advantage of stull timbering for levels is that th
below can be readily broken through to level above
out disturbing the waste and debris which accumul
under exhausted stopes.

Stulls and posts may be used in steep-dipping veins, 12 to 20 ft wide, with
The stull is set with a flat underlie (generally in hitches), with posts under bot
at intermediate points if required.

Drift sets (Art 21) are common for protecting backs of levels under stopes in narrow veins with weak walls; like stulls, they are placed and lagged after the cutting-out stope is broken. HALF-SETS are used where one wall is weak; THREE-QUARTER SETS, where both are weak.

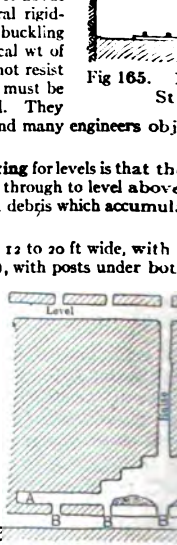

Fig 167. Level-pillars
Stope (sec in plane

Pillars of ore (level-pillars) may be left over level at bottom of overhand stopes; Fig 167, from Truscott (30), shows Rand practice (Art 41). In this case, stopes are opened from a sub-level (stope-drift) *A*, and connected with it by short raises *B*, in which chutes are built; wedge-shaped piles of ore, collecting between chutes on top of level pillars, are cleaned off by shoveling when stope is finished. Pillars may sometimes be recovered prior to abandonment of level. For factors governing choice on the Rand between level-pillars and timber, see Art 41. In open stopes, choice usually depends
ative cost of timbering, extra cost of the sub-level and net value of ore left in p

Packwalls may be built above level on flat dips and holes left in them
for chutes (for detail, see below under Support of walls). Need for protecti

rotection is necessary where dip is less than 20° 0° to 40°, see Art 38 to 41.

rs of ore are left where it is necessary to keep lars may be also required to support walls. See

an 40° to 45°, men can stand on and work upport being necessary; on steeper dips, tim-

Low-grade or waste portions of
shoot are usually left as pillars;
ary pillars of ore (as level-pillars)
mon; use of pillars for permanent support is confined to low-grade orebodies, us
extensive deposits lying on flat dips. For examples see Art 39 to 41.

Control of hanging wall over entire mine, in veins worked by open ov
stoping, may be effected as follows:

(*a*) In veins where ore is in shoots, the barren areas often serve as pillars; su
individual stopes is obtainable by one of the above methods, depending on size
and character of walls, and stopes will remain open indefinitely or cave after th
been abandoned. For permanent support to protect shafts, surface buildings,
hausted stopes may be filled. (*b*) Where ore is continuous over long distan
hanging wall may be supported on permanent pillars of ore. Flat-dipping, lo
amygdaloid copper deposits (Mich) furnish an example of this practice (Art 40).
continuous orebodies, stoping on each level may be carried to property line or to
ore, leaving temporary pillars, often of large size, to support roof. As much as
of the pillar ore is then mined, retreating from boundary toward shaft, and the hang
caves over robbed areas (see Clinton iron ores, Art 39). (*d*) In continuous oreb
good grade, or at great depth causing heavy pressures, levels may be driven to bou
before stopes are begun above them. Ore is stoped in blocks, starting at boundar
being mined before work begins in next one toward the shaft. Size of block is adju
pressure, kind of roof, and speed of work, so that the stope can be kept open with
until finished; the hanging wall is then allowed to cave and work repeated in a
block (see Calumet & Hecla, Art 38). The foregoing remarks apply to open stop
support of walls by filling, see Filled stopes, Art 59–67.

Handling ore. In STEEP-DIPPING VEINS, ore broken in open overhand
goes by gravity to level below. Loading chutes are built in openings i
timbering or pillars at intervals of 15 to 30 ft (for details, see Art 91).
mum angle on which ore will slide depends
on character of ore and footwall; soft ores
often slide less easily than hard (see Bir-
mingham, Ala, Art 39). Angle of friction
varies with ore; an irregular footwall
causes ore to hang; minimum angle, usu-
ally about 40°; varying from 35° to 45°.
In open, overhand work, no ore is stored
in the stope except the small amount left
on level-pillars or to protect level tim-
bering. WING STULLS (Fig 171) (winged
stulls or wing chutes) are sometimes used
to facilitate handling ore in steep-dipping
veins, where all the vein matter is sent to surface. They permit some s
in stopes, obviate necessity for lagging all the stulls, and permit use of

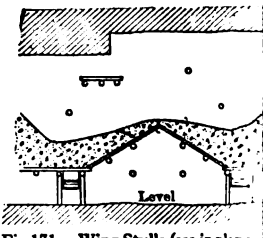

Fig 171. Wing Stulls (sec in plane

F is a cross-sec, showing former method used in upp of Mizpah vein; width, 5 to 30 ft; dip, about 70°; w is dry andesite, which will stand for a long time. broken averaged $15 to $25 per ton; no sorting done ground. Entry was by vertical shaft; level interval,

First row of stulls was horiz, 8 or 9 ft above level, a ported by 2 or more posts on sills wedged between walls of drift. Succeeding rows were set as usual at vertical i of 6 to 15 ft. · Plank lagging was used for platforms protect stulls at level; wing stulls (Art 36) were often em Stulls were 8 in or less in diam, braced in wider part vein by struts to stulls above and below (Fig 175). stope broke through to level above, the sills there were up from the stulls below. Some stopes have remained o 8 years; many are filled with waste to protect later workings. Recent practice square sets for wide orebodies (110, 188).

38. Examples of Practice, Open Overhand Stopes (Stulled Stop

Calumet & Hecla mine, Mich (67). Calumet conglomerate bed, d to 39°, width 10 to 25 ft, has been worked a distance of about 2 miles al strike. Shelly diabase hanging wall gives trouble, especially at the great of present mining (Art 17). Tenor of ore mined is 1.75% to 2% copper For ore occurrence, see Art 40.

General plan of mining in the conglomerate bed differs from amyg practice (Art 40), because of the weak hanging wall and great depth of a retreating system is required by these conditions and also by high te tures at depth, which necessitate good ventilation at working face; in a ing systems, much of the air current is apt to short-circuit through old close to shaft. Stoping is begun either at the boundary or midway betwe jacent shafts, retreating toward shaft; small blocks are stoped rapidly open temporarily by stulls and then allowed to cave; the only pillars l the shaft pillars, extending 50 to 75 ft along strike on each side of shaft; are robbed after hanging wall has settled around them, beginning at and retreating up the dip.

Development. For practice in locating shafts, see Art 17, 18. Le terval is about 100 ft; higher stopes can not be worked out quickly eno allow control of hanging wall in lower portions of stopes.

Drifts are 8 by 8 ft, and follow the footwall to take advantage of better grou well-marked slip; double-track drifts in Red Jacket workings are 7 by 11 ft; drif

ficult and costly to maintain. A 7 by 7-ft raise is n the end stope on the level, for ventilation and to as stoping progresses there is enough open space ese purposes.

stepped-face stopes are carried, a cutting-out th of lode for full length of stope; successive

GANG comprises a boy to run hoist, timbermen; on ar age this crew sets a 2 batteries per shi Hecla, in stopes 14 ft wide; at Red where hanging poorer and stopes to 25 ft wide (aver aver duty is 3 batt 2 shifts (sometimes battery per shift). (hemlock) in 1912 to $8 each. Grou stulls in batteries use of smaller and c timbers. Batteri well adapted to fl and conditions in conglomerate mine in stopes much ove 25 ft wide they ar tionable. PARTIAL ERY OF TIMBER is possible if stope length is such that excessive weight does no on lower part of stope before the block is mined out. Amounts of timber recovere widely; in some stopes up to 20% of the total is reclaimed. Recovery is done by b footwall under batteries with pop shots; before shooting, rope from the hoist is tied timbers so that they may be pulled out without danger to men; much lagging is under loose rock and lost. Timbermen receive $1.50 to $1.75 for recovered stulls 14 in good condition; they work at robbing either after shift or after finishing their timbering. HANDLING STOPED ORE. Broken ore slides or is shoveled to first batteries above level, between which chutes are built and ore scraped from the cars; bottom of chute is sometimes lined with steel plate, or entire chute is l hardwood. In S Hecla, 1st or 2nd row of batteries above level is lagged from 4 ft above footwall, to prevent occasional falling roof slabs from injuring trammer

39. Examples of Practice, Open Overhand Stopes (Support by Pillars o

Clinton iron ores, Birmingham, Ala. The orebodies are beds of hem occurring as interbedded members of a series of sandstones and shales. extend many miles along the strike and have been opened over 2 000 ft o Leaching has removed lime from upper parts, producing an enriched s for varying depths down to 400 ft on dip; below this, ore is hard. W. R. (190) and E. C Eckel (191) give following data: thickness of beds, 10 ft; dip, 8° to 50°, but usually between 18° and 30°; hanging wall, largely stone; footwall, shale.

Method of mining. Entry is by inclined shaft in the deposit; level interval 65 ft. Drifts, 12 to 15 ft wide, run from shaft each way 60 to 100 ft; thence, the tinue as drift-stopes (locally, rooms), extending up the dip 20 or 30 ft above the Raises, connecting levels at points 60 to 75 ft away from shaft, serve as manwa airways and also inclose pillars to protect shaft; other raises connect levels at intervals (Fig 178) (192). Drift-stopes are driven to limit of economic haulage levels; then pillars between levels are robbed, retreating toward shaft. Robbing m depend on character of ore, dip of bed, and the level interval. In very high lifts ore, which does not slide readily on footwall, horiz slices are taken off lower side of

ig 179). Hard-ore pillars are robbed by cutting off
l joints divide orebed into diamond shaped blocks

nton Iron Ore Mine, Birmingham, Ala; Sec in Plane of Orebed (after E. F. Burchard)

he bed worked is from 2.5 to 4 ft thick, be-
30°.

Method of mining. Entry is by single-track inclined shafts in footwall, with drifts at 100-ft intervals along dip. First mining consists of driving small stopes (rooms) up the dip at intervals of about 30 ft, with 20-ft pillars between them. An arch pillar 10 to 20 ft thick is left below levels, broken by small raises for ventilation. Most of ore is robbed from pillars on retreating. 8 shafts were operated in a distance of about 4 miles along strike; length of shafts, 400 to 1 200 ft; 370 men mined 700 tons per day; production per man-day, 1.5 to 2.2 tons; aver cost, about $1 per ton. 10 to 20% of total ore is left in pillars, or is unrecoverable because of faults or other disturbances.

Details. Size of drift-stope depends on strength of hanging wall; in Osceola v of C & H Co, South Kearsarge, Osceola Consol, Ahmeek, and Centennial mines, it 9 by 19 ft; at Allouez, where hanging is s in many places, size is 9 by 18 ft; at W where hanging is strong and lode wide, it 25 ft; at North Kearsarge, 10 by 16 ft. advance is slower than in drifts, but cost pe ore broken is less owing to larger size of also stoping can begin at once. Better ve in levels results from this practice, and bette tunity to follow lode. Disadvantages: (*a*) break low-grade ore which should be left; where poor ore is encountered, the area of is reduced to about 8 by 10 ft; (*b*) stoping a stoping sometimes crowd and interfere w other, owing to slow advance of the latter.

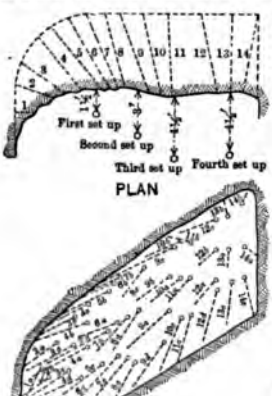

Fig 180. Drift-stope

shows a typical drift-stope in Osceola lod round resembles the side-cut for drifts (Art cut is on hanging wall, which has a well-defi and is first advanced 6.5 or 7 ft by 6 to 8 to 3 ft deep; 30 to 40 holes are required to round, depending on ground. Drills are on columns; all holes are blasted at end of sh Osceola lode, the face is squared up about per month (52 shifts); aver advance, 48 ft. sarge lode, about 8 cuts per month are blaste the ore breaks better, the aver monthly ad about 52 ft. Table 34 gives aver cost of a 12 drift-stope at Mohawk mine, in 1909 and 1910. In this period, ore broken per 2-ma drill per 2-shift day was 30.3 tons in drift-stopes and 22.1 tons in 9 by 16-ft cros

Stoping (67). Stope widths vary from 8 to 20 *ft*. GENERAL PLANS o (*a*) A stope of profitable width, usually 8 to 12 ft, is first opened along l wall; later, any ore occurring below the arbitrary footwall of first stope is broken in benches; this method is followed in Osceola workings of C & H Co; (*b*) Stope follows footwall. Ore less than 12 ft thick is broken in one operation; where thicker, a stope 10 to 12 ft high is advanced a short distance on footwall, then ore on back is blasted down. Opinions differ as to best method: under plan (*b*) it is difficult to reach and trim the hanging wall in stopes 16 to 18 ft wide; under plan (*a*) the mining of f ore starts at top of stope, for breaking ore onto the fairly smooth floor stope; this leaves less ore to be shoveled out when stope is finished tha floor is mined up the dip.

SARGE MINE. Aver width of lod dip, 38°; level interval, 125 ft. stoped in blocks 20 ft along st half the level interval on dip, o broken in slices parallel to dip; is mined in 1 month. Upper similarly mined; several lower st usually finished before the uppe gun. Pillars are usually left in stopes at top of drift-stope and a of upper stope, but their spaci strike depends on hanging wall. 10-ft chain pillar is left, except w els above are stoped out. ALLOU

Width of lode, 16 ft; dip, 38°; level interval, 125 ft. Lifts are mined in 3 series o each say 40 ft high, with pillars at bottom of each stope; poor hanging wall often pillars as close as 25 ft along strike. HANCOCK MINE. Width of lode, 8 to 10 ft; di 45°; level interval, 100 ft. Drifts, 6 by 7 ft, are enlarged by a cutting-out stope Back of level is timbered with stulls 4 to 6 ft apart, lagged with 4 to 6-in poles. A 2 by 4-ft hole is left in lagging at 25-ft intervals, with a sollar under it about 4 ft above track. Some broken ore remains in stope to protect lagging and aid in setting up drills; the rest is drawn onto sollars, sorted and loaded. Ground is good, requiring no stope timber. Pillars are left where ore is poor, also a chain pillar, 6 to 10 ft thick. QUINCY MINE. A lode about 10 ft thick, dipping 38° to 54°, is worked at great depth. Drifts 7 by 6 ft are run partly in footwall, followed by a cutting-out stope with back 18 ft above floor of level. Back of level is timbered with stulls, from 15 to 24-in up to 3 ft diam, set apart, without lagging; this is stated to be cheaper and safer than wider spaci lagging. A 5-ft space is left between stulls every 15 ft, and partially lagged, lea by 5-ft chute opening which delivers ore onto a sollar over the track. Stopes contai ous pillars at irregular intervals; stulls support slabs as required; some artificial waste on stulls are used. A stepped-face, overhand stope is carried. When stope is rock is blasted out of footwall and piled on stulls over the level to a height of 30 as the hanging wall settles, stulls are compressed until the rock filling takes the

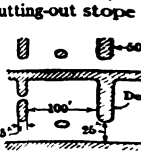

Fig 182. Stoping, Mine (sec in plane

Retreating systems are attempted in most amygdaloid mines; es as depth and consequent pressure from overlying rocks increase. drifts or drift-stopes must reach the boundary before stoping begins abov output requirements sometimes prevent this. At Allouez, it is pla extend drifts to boundary before more than the first series of stopes is at other mines, single stopes are opened successively, as far out from development allows, until the drifts reach property lines.

Besides increasing the difficulty and cost of maintaining drifts, the practice ning stopes before drifts reach boundary has following drawbacks: (*a*) blasting injures tracks on level; (*b*) mucking in stope and in drift or drift-stope inte small pieces of ore rolling from stope onto rails often derail cars; (*d*) danger fr falling from stope into drift; (*e*) sometimes a stope caves, and ore from point must then be run to level below; this is troublesome and costly, especially on fl

Arguments in favor of combined stope
Hoover (20) and Truscott (30): (*a*) on
dips, the upper part of stope has all the a
tages of underhand stopes, with added fac
for storing waste in the overhand stope b
(*b*) with a low dip, considerable ore can be
eled from the underhand part to level a
thus reducing transport distance in stop
shaft; (*c*) pillars, if required, are easily fo
er (heel) of stope; (*d*) men may keep close to face of stope in going to and
(*e*) face of stope is carried back on a general line parallel to raises; hence, b
on stope floor in lines roughly parallel to dip; this is advantageous with me
pe transport, as swinging chutes (Art 92). (Combined stope is little used o
Rand; advantage (*e*) is the most important. Author.)

aking ground in stopes. Aver stope width is about 5 ft; mini
about 2.5 ft. Factors governing widths: (*a*) thickness of reef; as
ck as possible is mined; (*b*) dip; narrower stopes are possible on
n flat dips; (*c*) bedding planes near reef may form economical wal
to; (*d*) method of drilling; narrower stopes are possible with hand
with small drills, than with large piston-drills.

lls. In underhand stopes, holes are parallel to dip, but are flat where
is frozen to wall. In overhand stopes, hand miners point holes slightly down
hammer boys are inefficient in drilling uppers); a rill-cut (also customary wit
drills) is taken with a much flatter inclination than in Fig 180. From 2 to 5
break from foot to hanging, the footwall hole being fired first, to open the face.
round, in stopes of aver width, hand holes are about 3 ft deep; machine holes, de
per less than 5 ft wide, hand holes aver 2 ft deep. Drilling is single-hand
hoe; natives drill one 3-ft down hole per shift in aver ground, or two 2-ft ho
round; speed is less for dry holes. A 3-ft hole breaks an aver of 1 200 lb.
city of labor makes machine drills desirable in all but narrowest stopes.
drills are in general use, but constant attempts are made to replace them by li
suitable for narrow reefs. In 1909–10, competitive tests were made by ru
different size and make for 215 shifts in stopes of varying width; a 2¼-in, a 2
to 2.75-in light piston-drills survived the competition; their aver drilling speed
rock were 61.2, 58.4, 52.8, and 52.6 ft per 8 hr. Each worked 43 shifts in an
width of 30 in, 3 shifts in width of 33 to 36 in, and 1 shifts in 36 to 40 in, a
all they can work in narrow stopes. Compared with hand drilling, tonnage ho
to 5 in favor of machines; cost of explosive, 6 to 5 in favor of hand work;
machine and hand drilling were about equal, but labor cost of hand drilling
than for machines. Banket is harder to drill than aver vein quartz in U S.

ssures (70 to 75 lb) were used; due to these condi-
pe-drills could not compete with piston-drills (195).
f all kinds were in use on Rand, 58.4% large piston-
% stope-drills, and 3.1% plugger-drills (196). In
s was still done with large piston-drills, but use of
nd hammer-drills is increasing. In regular stoping,
and 6 tons of ore broken per shift; 1 white miner
36 gives data (see also Brakpan mine, Art 31).

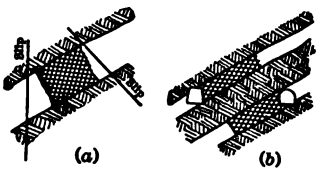
more pillars are left in lower than in upper part of stope. Machine stopes require pillars than hand-driven, due to shattering action of heavier blasts. Under aver tions, CHAIN PILLARS are left; in weak ore or under poor roof, both above and below minimum thickness, 5 ft. Work in adjacent reefs may make it desirable to chang tion of chain pillars, to insure their position (Fig 185 *b*). SHAFT PILLARS to 12 ft wide. ROBBING OF PILLARS be soon as the area containing them can be doned; owing to robbing in outcrop and increased pressures in deep-levels, movements of hanging wall have occ crushing stope and chain pillars and ir cases affecting shaft pillars (81); sand has been adopted to prevent further t (Art 93). STULLS are used locally to s slabs near working faces. Imported in 1915 cost about $83, inferior local t



(*a*) (*b*)

Fig 185. Arrangement of Pillars with Respect to Slips, and in Adjacent Reefs (after T. Johnson)

$26 per M; hence its use is minimized (79). ARTIFICIAL PILLARS, in form of pac (Fig 170), often replace chain pillars. In stopes, packs are also built of coarse Waste-packed stulls (Fig 152) are common supports, especially in steep-dipping unde stopes of outcrop mines; they also protect men in bottom of stope from falling Waste-filled CRIBS or PIGSTIES are often used, forming convenient support of roof a pillars while being robbed (Art 31, 36). For levels some engineers prefer them to pack

Handling ore in stopes. Where dip allows it, ore slides on footwall t level; on the usual dips of 25° to 30°, it is handled by mechanical de to avoid shoveling (see Art 92; also Brakpan mine, Art 31).

42. Pillar and Chamber Workings

The term denotes methods of mining in which large chambers are excav leaving pillars of ore for permanent support. Chambers may be mine underhand stopes, glory holes or overhand stopes (see also Mother Lode below). Support for men in overhand stopes is afforded by accumulati broken ore (Shrinkage stopes, Art 68), or by square-sets (Art 45 *et seq*); chan are rarely filled with waste to support men (see Rimogne quarry, below).

The method is a development of room and pillar work in beds (Art 32), for masses or wide veins. In typical cases, workings are a series of large open stopes arated by a network of vertical and horiz pillars of ore. Synonymous term CHAMBER WORKINGS, PILLAR WORKINGS, ROOM AND PILLAR, PILLAR AND STALL, RO (see index for other use of same terms; also Art 104–6).

Chamber workings are a very old form of mining, obsolete for metalliferous de except in rare cases; they are useful for exploiting cheap and abundant minerals, a or slate, where much of the deposit (40% to 70%) can be sacrificed in pillars for sec cheap support and low mining cost. Recovery of pillars is generally costly, ofte possible, and workings are left in such shape that a change to other methods is dif

Requirements of method: (*a*) large deposits, as masses, wide veir thick beds; (*b*) deposits of strong mineral or rock, with strong walls, will stand unsupported over back and on walls of chambers; (*c*) cheap erals, which will not pay cost of installing other methods; (*d*) deposits of form value, as no sorting is done in chambers.

Examples of practice which follow show variations and applications of the meth

Tilly Foster mine, N Y. Orebody is a steep, lenticular mass of strong magn embedded in gneiss; in horiz sec, it is about 200 ft wide by 300 ft long; dip, about It has been mined to a depth of 600 ft. Fig 186 shows method of mining part o deposit. An inclined shaft was sunk in footwall, with wide drifts at 100-ft inte along footwall to ends of orebody. From drifts, rooms 24 ft wide, with 20-ft pillars, carried across to the hanging wall. They were excavated overhand as shrinkage s (Art 68). A timbered crosscut in middle of each room connected with footwall

re raised to within 15 or 20 ft of level above, leaving r whole area of orebody. When a room was finished, oom ore- fill pil- part l by

Fewer raises are run ft deep) are drilled in top, bottom and sides of in- lar and all fired together. Drilling in both pillars drills and plugger-drills; former make about 32 ft

STANFORD LIBRARIES

per shift. In 1911, for blasting out 1 pillar, 2 433 holes were charged with 40% dynamite and fired simultaneously, breaking 175 000 tons.

Cost per ton, for mining 377 510 tons in year ended Nov 30, 1912, was: mi timbering (labor), 13.8¢; general underground and tramming labor, 9.56¢; e 9.97¢; candles, 0.46¢; drill parts and hand tools, 2.1¢; shops (except drill parts tools), 0.63¢; compressor and power, 2.69¢; lumber, 0.28¢; sundries, 1.58 41.07¢. Wages, $3 to $4 per 8 hr. Breaking ground is thus very cheap; cost sives is increased by necessity for blockholing large pieces in chutes.

For successful APPLICATION of this method, the orebody must be large, fairly of too low grade to permit use of filling or timber, and with footwall steeper t ADVANTAGES: (*a*) little mucking is necessary; (*b*) no timber except for chutes; nomical use of explosives (Table 29, Ex 6); (*d*) drills have large capacity in pil as they drill continuously without blasting delays on each shift; (*e*) method is

42. Sub-level Stoping

This method, also known as sub-stoping, was developed in Michig mines about 1902. It is an open-stope method and distinct from s caving (Art 76, 77). Following data and drawings are from F. W. Sper McDonald, and F. C. Roberts (208).

Type of deposit mined by sub-level stoping in Mich includes "p and narrow ends of large lenses; in general, steep-dipping, tabular d 12 to 100 ft wide. Ore should be free from slips, and strong enough fo to stand after trimming and benches to stand under their own weigh hard ore increases cost of driving sub-levels and is a disadvantage). must be firm, or they will cave and mix with ore, and overlying capping be strong, so as to permit stoping of large panels or blocks.

Development. Shafts or other entries should be outside of the oreb mining eventually causes walls to cave. Level interval, 100 to 150 f cally, each level a main haula from which cr are run to the w outline the depo

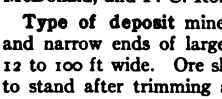

Fig 194

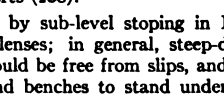

Fig 195

Chute-raises are from drift and cr to about 25 ft abo floor. Drift and cr are planned so th ters of raises are 15 to 30 ft apart; in 25 to 40-ft orebodies, raises alternate on o sides of haulage drift; some wider bodies have 2 parallel haulage drifts, connected a vals by crosscuts, to facilitate motor haulage. At end of deposit (or at end of panel to be stoped) a raise is put through to level above. Fig 194 shows procedure when end of orebody slopes forward. The triangular block *ABC* is broken by underhand stoping and handled to the level through the end raise; and ladderway and sub-levels 1, 2, and 3 are driven. If end of deposit slopes backward or is vertical, sub-levels are started from end raise as well as from ladderways (Fig 195). sub-level (No 1) is at tops of chute-raises; vertical interval between sub-levels, 25 ft; they are closer in soft than in hard ore.

Fig 196

nsists of a single drift in middle of the deposit. sub-level No 1 (Fig 195) is first widened to bout 12 ft wide and of same height as sub- deposit, and worked back toward ladderway.

f chute-raises, and uppers in back of breast stope, unnel shape to tops of raises (Fig 196). One round nigh across width of deposit and about 12 ft along raises and to chute gates in main level. After

rinkage methods (Art 68–70). In sub-level stop- round, but where the back will stand unsupported atter would generally be preferable. (*b*) Square- oice exists, it would be based on relative cost of mber for square-sets.

STANFORD LIBRARIES

Field of use seems to be in orebodies with good walls, which are to or otherwise unsuited to caving (Art 71 *et seq*), and in which the ore is to to use shrinkage methods and yet not soft enough to require square-sets

44. Summary of Open-stope Methods

Applications. These methods, employing pillars of ore for per support of walls, are best suited to low-grade orebodies; they sacrifi of the deposit to secure low mining cost. Caving methods yield hig traction than open-stope methods, and compete in cheapness with them fo low-grade deposits. (For limitations of caving, and types of orebody to it is suited, see Art 83.) Open stopes are in general limited to orebodi strong walls; in overhand methods, the ore must be strong enough to unsupported over backs of stope, as is true also of most underhand w wide orebodies (Art 34, 35). Strong ore is also required where ore pill relied on to support walls. Field of open-stope methods employing ore for permanent support is in beds and veins dipping less than 35° to 45° massive deposits where vertical pillars can be left. Stulls for supportin slabs, etc, are usually limited to a max length of 20 ft (Art 36 to 38); se vidual methods, Art 29 to 43, for their applicability and limitations.

Underhand methods. ADVANTAGES: (*a*) all drill holes are down holes, drill this avoids dust, is advantageous for hand-drilling with unskilled labor, and use of efficient plugger-drills. In general, breaking ore costs less in underhand overhand stopes; (*b*) miners stand on ore while working, which is safer than ov stoping in a few cases in narrow veins of weak ore with strong walls; (*c*) und methods, where applicable, require less timber than overhand; (*d*) in general, fines is less in underhand than in overhand work. DISADVANTAGES: (*a*) danger, men work under inaccessible backs and walls, the height and area of which incr stope is extended, and loose pieces may fall; (*b*) due to above conditions, the leve val must usually be smaller than for overhand methods; (*c*) facilities for storin in stopes are poor; (*d*) broken ore from face collects at a single point, which ma fere with economical handling and loading.

Overhand methods. ADVANTAGES (not indicated above): (*a*) miners wor back of stope, where they can examine face carefully and take down loose groun are not exposed to danger from pieces falling long distances; (*b*) waste or ore is stored in stopes; (*c*) a greater variety of working plans is available than in ov stopes; any type of machine drill may be used, and by using a rill-cut (Art 36) holes may be drilled; (*d*) an open, overhand method may, if required, be chang square-setting, shrinkage, or filling method, far more readily than underhand s (*e*) gravity aids in breaking ground; (*f*) broken ore falls down the dip under the i of blasting; this allows handling of ore to the level below without mechanical on flatter dips than is possible in underhand stopes. DISADVANTAGES are largely t verse of advantages of underhand; in addition, support for men is necessary in ov stopes on dips over 40° to 45°, whether required by walls or not (Art 94).

TIMBERED STOPES

The term "timbered stope" is used here to denote stopes in which tim is the predominant feature of the method. Stulled stopes (Art 36 to 3 also types of timbered stope.

45. Square-set Method

Square sets were first used in the U S in 1860 by Philip Deidesheim Ophir mine, Comstock Lode, Nev. The method is often called the N square set system. It is used chiefly in overhand work; for its use in hand stopes, see Art 46.

dvanced by successive small excavations, each Timbers in adjacent sections are framed into s forms a continuous structure of horiz FLOORS, ted at their corners by POSTS (Fig 199). One hose at right angles to caps being GIRTS (ties, ft high, are 5 to 6 ft apart c to c, both capwise

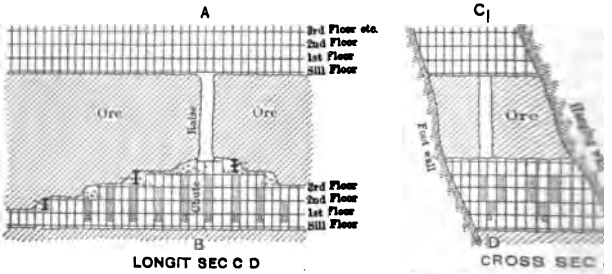

Fig 201. Square-set Stopes, Le Roi Mine, B C

may alternate with muckers at opposite faces. Faces of successive floors are ke 60 ft apart, to allow simultaneous work on each without interference (this di readily reduced to 20 ft at various mines in U S). Waste from development is into the finished stopes, but systematic filling is not attempted.

Details of open square-set work in stepped-face, overhand stopes ve stope-drills are used, ground is broken by uppers drilled from shovelin Main function of timbers is to support slabs, broken ore, and men. I ground, waste filling is generally required to prevent failure of timbers; of work is then modified as follows:

Square-sets are used for development openings, which can be laid out in straig corresponding to lines of stope timbers; crooked drifts are usually timbered wi sets, replaced with square-sets as sill-floor work proceeds. The floors are wid sections small enough for ore to stand unsupported until sets can be erected. The kept filled with waste, usually to within 2 or 3 sets of the back; under heavy pr only top floor sets may remain open. Haulageways are kept open on sill floor by the sets through which they run. Art 47 gives details of handling ore, waste, filled stopes. Occasionally, in very soft ground, the stope faces are advanced by

Domed or pyramid stopes. The work is so arranged that the general of the stope back is dome-shaped or pyramidal. They are commonly stopes, and have been used in massive orebodies of both strong and we under strong hanging walls. The arched back is partly self-supporti reduces pressure on timbers.

Fig 202 shows this method at Centennial-Eureka mine, Tintic, Utah, for mi irregular chimney, 350 by 100 ft in cross-sec, dipping 45°, and over 800 ft deep.

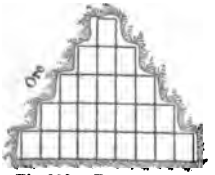

Fig 202. Domed Stope, Cross-sec

are fairly strong limestone, but in many places ore mined with a pick. Level interval is 100 ft vertical raises between levels near one end of orebody. Set 8 by 8-in timber, with sills 2 sets long laid parallel dimension of orebody. Work on sill floor starts at t and when a square, 3 sets on a side, is completed, a set is placed in the raise. Sill and 1st floor are then simultaneously; when the 1st floor is 3 sets square, floor is begun, and so on. Crib bulkheads are nece keep stopes from caving (Art 52) (210).

L. S. Cates describes similar work at Bingham, U irregular replacement orebodies in limestone or bet quartzite foot and limestone hanging wall (211). Ore is in shoots, 50 to 200 ft wi to 300 ft long, and in places 600 ft deep; dip, 0° to 90°. Open pyramid stopes a

vall firm. Space for only one set is excavated in set long. From a drift near center of orebody, ngitudinally through it. The sill floor is opened then a row of lead sets is begun on the 1st floor, ning on any set. Each wider than broken ore

and filling may be moved 1 set higher. Slides may converge in 4 directions tow and many variations are possible. Their use does not entirely eliminate sho

Pockets or bins for storage are sometimes used in open square-set stopes. Th by putting lining around from 1 to 5 sets, terminating at the bottom in a may extend through the whole height of stope. Pockets reduce shoveling di may obviate necessity for wing-chutes.

Access to open square-set stopes is by ladders from level below. In f there may be a raise to level above, or chutes built to include 2 rows of sets, compartments being a MANWAY. In heavy ground, these are harder to keep single compartment or "blind" chutes, but the manway is not only a tra through filled sets, but facilitates repairs to the ore chute and clearing it w

Filling is obtained in part from sorting, or from breaking was grade inclusions in the orebody. For running in filling from outsi a raise to the level above is necessary. Filling is distributed by shovel or cars, depending on size of stope and distance between waste raises.

Practice in handling filling (see also Rill stope, Art 46). At METCAL friable, massive orebodies, stopes are kept full of waste to within 1 set of the ba (from surface workings) is distributed from a small raise in a corner of the st venient arrangement, because, by beginning mining of each floor at this point can be kept close to the face without interfering with shovelers (152). At H MINE, Leadville (statement by G. O. Argall), orebodies are massive repla limestone and porphyry, with flat dips. For opening stopes, main haulag driven under the orebodies, with raises 50 ft apart. Waste comes from d work, where a raise exists for dumping it into the stope; if there is no rai obtained by driving inclined raises into back of stope, or by drifting into wa ARD MINE, Butte. Wide vein; soft ore; block system of stoping; stopes, (Art 46). A 2-compartment raise is carried to level above in middle of each A car on a temporary track, laid lengthwise on shoveling floor, in middle of tributes filling, which is kept within 2 sets of back. Side walls of stope ar prevent runs of filling when adjacent blocks are mined. Posts of the outer se top and bottom, to those of next row by spiking on 2-in planks. Lagging, 2-in plank, is placed on stope side of posts. Planks are spaced 5 to 6 in apart cheaper and have longer life, but take twice as long to place. Open lagging i to allow fine filling to run through and fill space between lagging and walls. space prevents sets from swinging, and reduces loss of ore on sides of stopes filling when the block alongside is mined. One man places lagging and distrib in a 50 by 25-ft stope.

Timbers are handled most cheaply when lowered or dropped t raise from the level above; 1 compartment of a waste raise may be u Lacking access to stope from above, timbers are hoisted from below b lass, or electric or air hoist. In filled stopes, TIMBER CHUTES are s kept open through the filling by lagging and lining a vertical row of se a manway or ore-chute; or a timber slide may be built in a corner of

48. Dimensions of Square-sets

Horizontal dimensions. Table 39 shows that practice favors s 5 by 5 ft in plan, with floors 7 to 8 ft apart.

C. T. Rice states (80): (*a*) Posts should be far enough apart to give shovel to allow for right and left-hand shovelers, they should be equidistant capwise wise. A clear space of 4.5 ft is about minimum for efficient shoveling; hence, timbers, posts should be at least 5 ft 4 in centers. (*b*) Strength of ore limit of set, as the ground must stand unsupported over area of 1 set while timbers placed. Heavy pressure from weak ore may require smaller sets (see *e*). should be proportioned so that 1 round of holes breaks room for a new set, thu prompt placing and blocking of sets. (*d*) Large sets are desirable, in reducin of timber per ton of ore, but, in large sets the timbers are heavier and cost more and a stope started with a large post interval may become unmanageable if t

STANFORD LIBRARIES

safe bearing values, square-set joints are always strongest in the direction in tenons butt. For such conditions of loading, post-butting sets should be used direction of max pressure is vertical; cap-butting sets, where the direction of sure is lateral. Where pressures exceed safe bearing values, the joints are cr In cap-butting sets, ends of posts bear entirely on wood in cross grain, and und pressure the rate of compression is equal over the whole area of joint. In po sets, under heavy vertical pressure, the post tenons or HORNS must fail before grain wood in caps and girts can aid in transmitting pressure to the post. As compression is not the same in all parts of a joint, settlement in a stope is often C. T. Rice cites evidence (218) to show that settlement is greater and more in post-butting than in cap-butting sets, and that more auxiliary timbers are nee former to keep the floors level. Hence, many engineers prefer cap-butting sets vertical pressure, and practice is almost uniform in using them for heavy lat sure also, though arguments like the above indicate the superiority of post-but But, in heavy ground, filling follows mining closely and takes most of the lateral the smaller and more uniform rate of vertical settlement of cap-butting sets is argument for their use in such ground.

Square-sets may also fail by "jack-knifing"; posts swing out of line and ev girt or cap drops, allowing adjacent sets to collapse. Hence, wide seats for caps are desirable, and are commonly given in cap-butting sets. In post-but wide seats are obtainable only by reducing the size of the post horn. Long small cross-sec are always objectionable, as they break too easily. With timbe by 10 in, post-butting sets with adequate shoulders and horns are readily framed times, to give a wider bearing for either girt or cap, horns on posts are not section; they require a complicated framing machine. Note that girts are mo pull away from their seats under light than under heavy pressure.

Empirical rules proposed for framing details: (*a*) length of the p should be less than its least cross-sectional dimension; (*b*) girts a should have a seat on the post not less than 2 in wide; a wider should sirable (218). SIMPLE FRAMING is best, especially for hand framing butting sets are generally simpler and cheaper to frame than cap-butt but the difference is small when framing machines are used. Com joints resist distortion better, because of the numerous shoulders, advantage is doubtful, as corners are points of weakness at which begins, and such joints are difficult to assemble if the timbers have b slightly crushed. SYMMETRICAL FRAMING is best. It costs less to place when the posts can be set either end up; caps and girts also should be s that either of two opposite faces may be placed upwards.

Examples. Fig 212 to 219 show post-butting types; Fig 220 to 227, ca types. At Copper Queen mine, Ariz (Fig 212), both cap and girt are dappe framing is used at Broken Hill, Australia, with a post horn only 4 in square. A 8 by 10-in girts are framed square on each end, the joint thus becoming the same Cananea, Mex (Fig 217). Girts fail at their bearings on the post; an 8 by 10- is cheaper and has same bearing area as the dapped 10 by 10-in. But, narrow vide smaller support for floor plank. Fig 216 shows same type of framing, but timber. The narrow shoulders supporting caps and girts indicate the limit 8-in timbers, when the posts butt; they should be used for light pressures only

At the High Ore mine, Butte, the post (Fig 213) is unsymmetrical, with a 6-i top and 4-in at bottom. This secures a shallower mortise at top of set, whic to clean out and allows "flirting" the post (Art 53), if sets have swung sligh line; long, slender horns make flirting of posts difficult. Another way to reduce horns on posts of post-butting sets is to cut them of equal length and short leave a SQUEEZE-SPACE between them (Fig 215). At Vulcan mine the same used for 10-in and 16-in timbers, with post tenons 4 and 8 in square respectiv Squeeze-spaces are usually 2 in thick; if they are filled with a SQUEEZE-BLOCK of the posts bear entirely on cross-grain wood, as in cap-butting sets. Neithe spaces nor blocks are in general use in high stopes, as they allow excessive se Squeeze-spaces at tops of sill-floor posts may lengthen the time during which will remain open without reinforcement.

Examples. BISBEE, Ariz. Large, irregular masses of ore occur in limest
porphyry, with no well-defined foot or hanging wall; usually ground is heavy
be mined only in small sections. M. J. Elsing states (225): Sill-floor set de
nature of ground in which stope is started. If floor is waste, a flat-bottom pos
resting on a small block with 4 by 6-in spreaders between posts. If floor is o
mined from below, 10 by 10 sills covering 1 set are placed
capwise and braced apart with unframed 8 by 10 timbers
laid girtwise (known as a "cap-sill" and "tie"). "Mud-
sills" may be used instead, framed of 10 by 10 timber,
1 set long, running girtwise and braced with 4 by 6
spreaders. Cap-sill and tie are stronger, and are used
in either ore or waste around raises which must be kept
open (Fig 240). In very soft ground, even though floor
is waste, a cap-sill and tie give good foundation for sets
above, and, for supporting a floor covered with waste
filling, are easily caught up from below with stulls and
posts. In general, where floor is on ore and the ground
heavy, they are preferred to mud-sills. GOLDFIELD,
Nev. Sill-floor posts (10 by 10-in) have a flat bottom
and stand on 8 by 10 sills. 2-in spreaders are spiked to
sills between posts, but there are no braces between
sills. Lateral bracing for feet of posts is furnished by
a floor of 2 layers of 2-in plank spiked to top of sills (145). BUTTE, Mont. Amal
Copper Co often omits sills (80). Flat-bottom posts stand directly on the stope
on footblocks where the floor is low; 4 by 10 spreaders brace feet of posts cap
braces, girtwise. This practice is largely due to the time required to level
points on stope floor, for placing sills properly. In some camps, sills are bed
layer of muck for quicker placing and because the muck protects them when th

width of sets and size of car. Special timbering for turnouts is avoided by u tables; most engineers prefer timbering.

Timbering on walls. Standard sets are often impossible in min irregular walls of dipping orebodies. Square-sets must have firm supp footwall and follow the hanging closely enoug proper blocking of timbers.

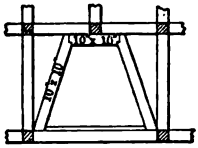

Fig 243. Arch Set at Turnout, Bingham, Utah

In firm ground, short posts, caps, or girts are use walls, with their ends in hitches or wedged agains Short posts on the footwall are GROUND POSTS (Fig of the bearing block *a*, and depth of hitch depend o of ground. CAP-SILL (butt-cap or butt-brace) is used on flat dips or soft rock, to tie the foot of the post to stope timbers and distribute pressure from the post over a larger area than that of the ground post. SHORT SETS are common on hanging-wall side. Fig 245 shows a form used by L. S. Cates at Bingham, Utah (211). Cap *a* is not framed into post *b*, but is spiked to it and supported by a piece of 2 by 8-in lagging *c*, spiked to *b*. Lateral motion of the cap is prevented by a brace of 2 pieces of 2 by 8 lagging, spiked in place and reaching to next set. In soft ground, a good but rather costly bearing for sets is secu ting into the walls far enough to allow use of full size se where the dip requires an offset in the floors. ANGLE SETS (Fig 246), or HALF-ANGLE SETS (Fig 247), are for following the hanging wall and supporting lagging. Angle braces and sets may also be used to support sets on footwall (*b*, Fig 244). Details of wall timbering are varied locally. In open stopes, lagging may be used on either wall over areas of shelly ground. In close-filled stopes, a exposed at one time is small, and lagging is rarely necessary. For use of lagg walls in the block system, see Leonard mine, Art 47.

* These figures are for a corner set (1 post, 1 cap, and 1 girt). † Bd ft in ro er is computed by QUARTER-GIRTH RULE: area of cross-sec = 1.97 × square rhich gives cross-sec of largest square timber that can be sawed from a given l

Data on framing. At ROSSLAND, B C, in 1903, round timbers averaging 16 were framed by hand. Aver work for 1 carpenter per 9 hr was 21 posts, or 21 6 caps. Cost per set was about 55¢ (wages, $3.50). Cost of same set, machine ot over 30¢ (209). At HOMESTAKE MINE, So Dak, in 1903, some 12 by 12 tim ramed by hand at 60¢ to 65¢ for a cap, girt, and post (wages, $3). Posts cost nore than caps or girts. Costs show that 1 man framed 13 or 14 posts, or 14 to r girts, per day (104). B. H. Dunshee gives following figures for BUTTE: 1 c rames by hand 10 posts, 10 caps, or 20 girts, in 8 hr from 10 by 10-in timbers. nd framing machine of the block type, with horiz and vert saws, operated by rames 300 pcs (posts, caps, or girts) per 8 hr. This is for 10 by 10 timber or rou o or 12-in diam. 2 sawyers, running a single-end block-type machine, frame aps, or girts, from 10 by 10 timber, or 200 posts, caps, or girts of round timber iam per 8 hr. Cutter-head type of framer (with 2 sawyers), used for framing th oints (Fig 237), makes 900 to 1 000 posts or caps, or 1 000 girts, per 8 hr.

R. H. Allen gives Table 42 (129). Mining is by hand drilling (see Table 25 for ore occurrence and mining method). Stope sets are of 16-ft logs, 7 to 8 small end; lagging is of 6-ft slabs; posts, 6 ft 2 in high, are placed 4 ft 8 both capwise and girtwise; stopes are kept filled with waste to within 1 fo Figures are for mining 17 253 tons, in 7 mo of 1912. Rate of exchange, 0.49 timbermen, $0.994; helpers, $0.7455; underground laborers, $0.373 to $0.6 all native labor. 16-ft poles, 6 to 9 in diam, cost $0.895 to $1.566 each; s per metric ton. See also Sec 21 for cost of labor and timber at mines using

55. Applicability and Limitations of Square-sets

In early days, the method was standard for mining nearly all large oreb U S. Increasing cost of timber, and introduction of shrinkage, filling, and cav have narrowed its field of use.

Open stopes. Experience shows that open sets do not afford support for weak ground; timbers rot, or more often crush unde caused by the extension of stoped areas. This is serious, as the large stopes may set up a slow crushing action ("creep"), which ex adjacent unmined blocks and renders their extraction difficult a The field for open square-sets is in orebodies too wide for stulls, and ground is strong, but requires prompt support to prevent slabs fa back and walls. These conditions preclude use of shrinkage stoping native is a filling method, the choice being governed by relative of these systems, as stated below and in Art 67, and by their rela

H. C. Hoover cites following cases (20): At Le Roi mine, B C, square-set 21¢ per ton; at Ivanhoe mine, W Australia, filling costs about 22¢ per ton of ber costs less than $10 per M at Le Roi; at Ivanhoe, $50 per M. Cost and

st of square-setting at Ivanhoe would be about 65¢

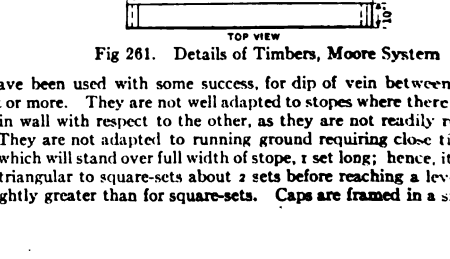

Fig 261. Details of Timbers, Moore System

F. S. Bradshaw furnishes data from Tonopah Belmont mine: Moore sets have been used with some success, for dip of vein between 75°, and width of 15 ft or more. They are not well adapted to stopes where there movement of one vein wall with respect to the other, as they are not readily r with angle braces. They are not adapted to running ground requiring close ti but rather to ground which will stand over full width of stope, 1 set long; hence, it sary to change from triangular to square-sets about 2 sets before reaching a lev Cost of framing is slightly greater than for square-sets. Caps are framed in a s

wing crosscut saw, with same number of operations by hand. Posts are framed by a swing saw, with posts. re-sets. per ton

stems

square- ng wall, a mine, was to The sys- oned in

used at ith soft At Argo- square- 30). Advantage claimed is that posts can be set n is such that square-sets can not be placed with posts superposed in the short time that the ground will hold. Stull timbering without posts will not hold; walls swell and often require lagging. Round timber is used; posts are 8 ft long, and 4 ft apart along strike; joints between posts and stulls are braced longitudinally by unframed sprags. Stope timbering starts from 2 stringers, one on each wall, blocked up from drift-set below, and separated by lagged stulls carrying filling. Swell of walls tightens timbers, so that they support filling even when drift sets are destroyed by mining the chain pillar from stope below.

Stringer sets (formerly used in Ontario mine, Utah, in wide parts of a steep vein) consist of a horiz cap (STRINGER), from wall to wall, carried by posts 5 ft apart. Caps are braced by girts opposite posts. No framing was done, 60 d spikes being used at joints. Max length of stringer, 16 ft; for wider stopes, 2 stringers were butted, with a post under the joint. These sets suited the solid quartzite walls at Ontario mine, but gave trouble when tried in weaker ground elsewhere. They require nearly as much timber as square-sets, and as much labor, when latter are framed by machine.

Fig 263 shows similar timbering at Morning mine, Coeur d'Alene, Idaho. Wall rock swells, causing side pressure great enough to broom out the ends of 24-in red fir caps, which are therefore protected by soft-wood blocking, removable for relieving pressure. Close filling is necessary; often within 1 floor of back. This system is in general use through the district for widths less than 15 ft (231).

FILLED STOPES

59. General

Definitions. FILLED STOPE, as the term is used here, is one in wh for walls and men and, at times, for back of ore is furnished by waste r sand, etc; materials so used are called FILLING or GOB. Classifi METHODS WITH CONTEMPORANEOUS FILLING, in which breaking of ore more or less closely by placing of filling; for descriptions, see followi filled square-set stopes (Art 45 et seq) may also be classed in this METHODS WITH DELAYED FILLING, in which filling is not an integral stoping method, but is introduced later to prevent eventual collapse o may be used in open, timbered, or shrinkage stopes. Examples: Me Art 35; Tonopah Mining Co, Art 37; Republic mine, Art 42; LeRo 46; Mitchell slicing system, Art 56; Homestake mine, Art 69; also and flushing, end of Art 64 and Art 93; also Art 110.

General plan. In methods (*a*) above, the orebody is excavated each practically an open or timbered stope, filled wholly or in part befo ground is attacked. Size of section mined before filling is adjusted of ore and walls; details vary with size and shape of stope and sourc methods of maintaining haulageways and of mining level-pillars are va strength of walls and ore and width of orebody. With few exceptio (*a*) are limited to overhand flat-back, stepped-face, or rill stopes (Ar

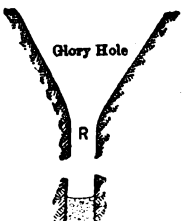

Fig 264

Source of filling. Cheapest filling is wast avoidably broken with the ore, which can be so the stope (Art 60); amounts of waste produced are usually insufficient, and must be supple other material.

Excess filling may be supplied by: (*a*) Shooting of lode; this obtains filling with little or no handling, ible if wall rock is strong; in weak rock, such excava a strip of unsafe ground alongside of ore in back of st suing, Art 61). (*b*) Driving crosscuts into walls; th duced is distributed laterally in stope in barrows o Inclined raises in walls serve same purpose, discha into the stope by gravity (Nevada Wonder mine, Art cuts and raises serve to prospect the walls, and henc able for obtaining filling where parallel stringers are a Methods (*a*) and (*b*) are used mostly in flat-back relatively small amounts of filling required in excess o sorting. (*c*) Using waste brought from surface; it may consist of mill tailin waste rock which can be broken cheaply in an open cut. Such filling, usually ground through FILLING or WASTE RAISES, is transported laterally along levels in cars (occasionally by belt conveyers) and dumped through raises into the stopes. Fig 264 shows mode of obtaining waste rock at LOS PILARES MINE, Nacozari, Mex (150). Glory-holes (Art 100) are opened in barren ground on the surface around raises *R*, which are 15 ft sq. Rock is broken with deep holes and heavy charges, and falls by gravity into the raise, at bottom of which is an offset connecting with drift *T*, and main waste raise *W*. Top of *W* is covered by a grizzly of heavy timbers 18 in apart, faced with steel, on which large boulders are broken. These raises terminate in bins, waste is distributed to stopes by electric haulage; total cost here of filling placed

STANFORD LIBRARIES

Sorting in stopes is usually possible only when ore minerals are
nized, where ore and waste differ markedly in appearance, or ore occu
bands or patches. Underground sorting is not feasible where fine
required to separate ore from waste.

Sorting diminishes amount and increases grade of ore secured. This may
and operating costs for handling and milling an ore, and give more profit than
by treating entire contents of vein; it also reduces amount of outside waste
filling. Sorting may result in a profit from ore of apparently too low a grade
illustrated by following figures from a western silver mine. An 8-ft vein

from H. Rose, in 1916 (235). Orebodies are in one shoot was 3 000 ft long, 600 to 700 ft deep, r ton, chiefly in silver. Hanging wall is usually fractured, with slips parallel to veins, and requires careful support. Flat-back overhand stopes with contemporaneous filling are common when walls are too heavy to permit shrinkage stoping, but strong enough to hold until stope can be filled (Fig 271). Economic max level interval is 165 ft, due to difficulty of maintaining timbered chutes in higher lifts. Besides the drifts in the vein, counter-drifts are run in the firmer footwall ground; crosscuts, 165 ft apart, are driven from these to the vein, ween crosscuts. Drifts under stopes are not kept tes and manways are built up from ends of cross- e (Fig 271). Filling comes partly from develop-

veniently, and so that winzes or raises will serve for handling filling to stopes. Proper connection should be made with main waste raises. (*c*) Ladderway offset from gangways and not be started on curves. (*d*) Two chutes and a la

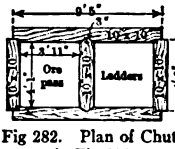

Fig 282. Plan of Chute in Fig 281

always placed near a raise, which serves as a starti stoping and for mining level-pillars. These state generally to all wide, filled flat-back stopes.

Sill-floor bottoms are of 10 by 4-in Oregon pine p 14 ft long, laid parallel to strike and close togethe floor outside of gangways. At SOUTH mine, bott on a 12-in layer of fine filling, because: (*a*) It is level the planking on a rough stope floor; the filling r ing cost, and the planks remain sounder. (*b*) Wh pillar below a bottom is mined, the layer of fines may be scraped out an inserted (Underhand square-setting, Art 45) before shooting out the ground. bottom reduces risk of runs of filling into the stope below.

Bulkheads or cribs are 5 to 7 ft square, of 10 by 10-in by 5 to 7-ft Oreg 279). Stope cribs are usually 12 ft apart, allowing use of 10 by 10-in or 10 by 6- 14 ft long, to catch up ground between; sometimes long "booms" are cant from top of a crib to support shelly ground. Cribs are not omitted in strong are spaced 15 to 20 ft apart without stringers; a special crew is kept busy o and wedging and blocking those in place. Cribs prevent small falls and g of loosening of large masses; they may rest upon planking, to distribute pre larger area of filling.

Recovery of timber. Gangway timbers and bottoms are lost. Methods ing crib timbers: (*a*) When filling approaches a crib, a new low crib is built c close to the old one; latter is then pulled down and the timbers reused. (*b*) 6-in timbers, 2 ft longer than crib timbers, are inserted in a bulkhead about 9 base at the time it is built; as a new layer of filling approaches, the projecting e timbers are supported on 4 10 by 6-in posts, and lower part of crib is removed. proceeds just ahead of the toe of the fill; the 4 posts are drawn out of the fill and chain when the next back-stope uncovers them. Method (*b*) has advantag remain in original position until fill is completed; in bad ground cribs are no

Filling. Residues from flotation plants, commonly used for filling, have p well in the stopes; at CENTRAL mine, broken rock filling ("mullock") comes fro Filling passes through raises to main level above stopes. At PROPRIETARY diam bore-holes, made by Calyx drills, have been employed for handling sand cost about 25% as much as a winze. Lateral transport to winzes serving stopes is in mine cars holding 2 500 lb; men or horses are used for tramming, depending on distance. Conveyers are used at several mines where much filling is handled; they are uneconomical if oreshoots are irregular and far apart. First layer of filling is about 12 ft deep, covering gangway timbers with 3 ft of material (Fig 279). Temporary chute gates are erected in stopes at bottom of winzes, and filling is distributed in side-tip cars, running on trestles of 2 by 1 which are subsequently withdrawn and reused. Operations of filling and layi bottoms proceed simultaneously, so that the layer of filling under bottoms may conveniently from toe of fill. In back-stopes, filling follows miners as closely the thickness of a layer being equal to height of slice taken; Fig 283 shows cedure, which leaves a 4-ft space under the back.

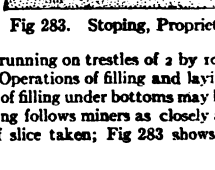

Fig 283. Stoping, Propriet

Mining level-pillars. Height to which flat-back stopes may safely be ca pends on their area, strength of ore, and on local conditions which determine wa In strong ore, entire lifts have been mined in places as flat-back stopes, the last mined in small sections, and stope bottoms above picked up on cribs. Usuall stoping is not considered safe when level-pillar above is less than 25 to 30 ft SOUTH mine, 30-ft level-pillars are mined by underhand square-setting (Art last back-stope is only high enough to allow a flat floor of square-sets to be ere of filling over entire area of stope (Fig 209, 210). from shafts, often require a level-pillar to stand untouched from 3 to 8 years time ground becomes heavy, and unsuitable for flat-back stoping. It is pro Baltic method as a retreating system, to shorten time before level-pillars ar a larger level interval might be possible, as well-built stone chutes stand wea for long periods. Width and dip of lode are also related factors influencing as chutes should be vertical, if possible (Fig 292).

Sorting is done carefully by special men; rock showing even a sp is sent to chutes. Large boulders are broken and the pieces exam decide whether fine rock, requiring shoveling, shall be classed as Few fines are produced in breaking, hence loss of fines in filling is s of fine waste, placed on top of the rock fills in stopes, eases work of sh may be recovered by skimming off an inch or so of this when the sto up. (See Mining level-pillars, below.)

Breaking ground in flat-back stopes is done with breast holes (Fig 289, 290).

C. T. Rice states that, at Champion mine, max burden on a hole is 22 in; tical row of 2 flat holes and 3 water holes to break a face 9 ft high. At Trim 1 flat hole and 2 water holes break faces 6 ft high; the same round often face at Baltic mine (1141). Holes are spaced about 5 ft apart across loc charged with 5 to 7 sticks of powder; 30% dynamite is used in company w tors prefer 40%. In 1912, drilling was done with 2-man piston drills (Ex 6, placed later by 1-man drills; in 1916, most drilling was done with Jackha columns. Distance between back and top of filling determines HEIGHT OF taken; enough muck must be made to afford a place to set up drills; for t between these factors see Fig 290; if filling is low, a high pile of broken ore ma by working 2 back-stopes simultaneously, with their faces close together.

Mining level-pillars (locally, "caving pillars"). Work begins the boundary, or at a point midway between shafts, and retreats to

A rill stope (Art 36, 66) is started from bottom of the raise; cuts are inclin repose of filling, which is 40°; miners work on waste, which is dumped th

fast as ore is sorted and rem is enlarged to dimensions all broken ore is then cleanc tion *L* of the 8-ft pillar rer the level is shot down from This allows dry-walls and stope above to drop; proje of the 8-ft pillar keeps op space 6 or 7 ft high alc Rest of level-pillar is mined Stope-drills are used, putt half-uppers, 6.5 to 7 ft d shift. Usual crew, 2 mac 2 sorters. After round at holes *C* are drilled. Then in *G* is sorted out and rem may take 1 or 2 weeks in cl stope. Next, round *B* is b runs in from above; sloping face of stope is kept open by the stub of pillar process is repeated. Holes at *D* for starting a new slice may be drilled befo is removed and while the back there is easily accessible. Practice of drillin before they are needed is a safety precaution, as the stub must stand for a time and the ground becomes dangerous to work under. In narrow parts strong ground, rill stopes for mining level-pillars may be carried with stepp 36). Ground is broken with breast holes, which are more efficient than u lode, but barring down takes longer, and this method is not so safe as that

Sorters work at *E*, and along face of pile of broken ore; waste rock ma sides of stope or dumped at *F*. Two chutes must be kept open, one for or

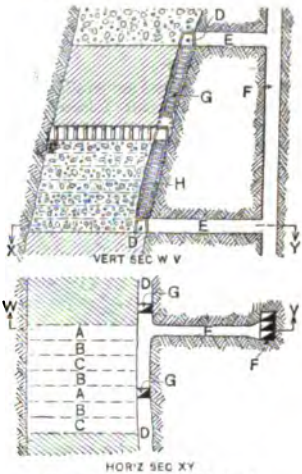

Fig 294. Crosscut Method

d 6 to 10 ft wide, or as wide as strength of ore e timbered with light sets, or stulls and head prevent runs of filling into adjacent workings.

OPRIETARY MINE, Broken Hill, N S W, where this y 10-in struts *S*, running along the sides of cross- osts; the back is carried by lagging on cross-pieces *D*; diagonals *E* are put in where required by pres- sure. Sets are about 6 ft apart; their size depends on character of ground and length of timber avail- able. About 67 % of the timber used is recovered on opening a new slice. The tapered shape of posts and the hole *H* (for inserting a piece of drill steel) aid in withdrawing them; or a chain and lever may be used (240).

Breaking ground. First openings in lowest slice of a lift are driven like drifts (Art 21); adjacent crosscuts cost less, as ore is free on at least one side. he ore is always free on the bottom. At CABEZAS t price for mining the lowest slice averaged 50¢ per

verlying filled stopes requires care. Plank or crosscuts in bottom slice, to prevent runs of below; sometimes filling becomes so compact sscuts may be spiled under loose filling.

m is usually 65 to 70 ft (246). Filling can to crosscuts, and each layer settles somewhat

STANFORD LIBRARIES

under weight of the back. Successive subsidences cause ore abo and increase difficulty and cost of mining upper slices; this effect in height of lift and weakness of ore.

At CHAPIN MINE, Mich, where this method was formerly used, settlemen a 100-ft lift are said to have occurred (247). At CABEZAS DEL PASTO MIN filling was coarse quartzite, quarried on surface, and so firm that no subside was noticed (248). At some places subsidence occurs because the top slic incompletely filled.

Several variations are possible. Haulage drifts *D* (Fig 294) need not be but may be in any part of deposit or in wall rock. Crosscuts *A*, *B*, *C*, m desired direction through deposit; large horses of waste may be left in pl shows application to an irregular massive deposit, opened by shaft *S*. Usu on a level is to outline orebody with *A*; then haulage drifts and crossc placed in best position; one arrange cuts for slicing is indicated by dott least one main waste raise *R* is d further detail and other variations, 245–249).

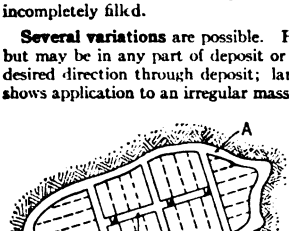

Fig 296. Crosscut Method Applied to Massive Orebody; Plan of Level

Summary. Crosscut method all complete extraction of large, weak almost any shape, without serious s ence. Cost of development is high, small level interval and frequent nece ing haulageways and waste raises in Cost of shoveling large amounts of is unfavorable to use of this method in the U S. Timber consumption will stand over back of a crosscut until it is filled; even in weaker ore, used than in top-slicing (Art 71–75) or filled square-sets (Art 46), which a methods affording complete extraction; caving methods are preferable if sur be supported. Crosscut method is sometimes advantageous for mining l bad ground over filled flat-back stopes (see Minn Iron Co, Art 62).

66. Filled Rill Stopes

General data are given in Art 36 (Fig 159, 160). Filling is ru stope through the raise from which it was opened, which enters the highest point. Filling is distributed largely by gravity. By i stope backs at the angle of repose of filling, the surface of the fi parallel to back of stope (Fig 297), and therefore convenient for sup and walls; a sloping surface of fill also aids in moving broken ore t

In narrow stopes, little or no shoveling may be required for handling fillir wide stopes, filling builds up under the raise in form of a cone and must be sho of stope; similarly, broken ore must be shoveled from sides of wide stop See Calumet & Ariz Co and Mt Lyell mine, under examples below, for mod shoveling in wide stopes. For field of use, see below; also under Compari back stopes, Art 67. Term "cut and fill" is used in several districts of U mining in filled rill stopes.

Examples of practice (for further data on breaking ground, see

Kalgoorlie, Australia (251, 257, 258, 146). Filled rill stopes are used in like deposits of gold telluride ores, occurring as lenticular shoots of quartz country rock, chiefly in amphibolite schist. Method is not applicable o than 35°; usual dips are steep. DEVELOPMENT. Ideal plan is to run level connected by winzes *W* (Fig 298) at intervals of 150 to 200 ft; winzes are sun wall to minimize handling of filling. A flat cutting-out stope, 7 ft high, is t are timbered with stulls for widths to 14 ft; for greater widths, use saddle-ba 36). Stulls are 5 ft apart, and lagged with 1-in poles covered with old filte of cyanide cases, etc, to retain fine filling. Chutes are started about 50 ft ap

arter points *M* (Fig 297). STOPING AND FILLING about 37°, and rill cut is generally adopted (Fig first opened at foot of winzes *W*. Broken ore is made by taking up 1 or 2 lagging poles, and waste above.

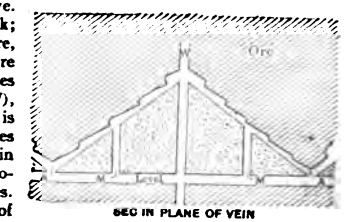

Fig 297. Starting Rill Stopes, Kalgoorlie

thick; n ore, *M* are stopes 297), ore is hutes 7-in pro- utes. ne of nning used

sture content is less than 25%; if wetter it tends used to distribute filling, as at *C* (Fig 298); then only one winze needs to reach the surface. Even with winzes on the hanging wall, some filling must always be shoveled in stopes to edge of rill. In rich ore, plank floors are laid on faces of fill to avoid loss of fines and help ore to slide to chutes; old filter cloths are sometimes laid under the floors. Floors are usually omitted, involving the removal of a few inches of filling with the ore from each slice (83). Stopes near top of lift can not be filled through original winzes *W*; auxiliary raises *R* (Fig 298) are put up to handle filling.

Superior & Boston mine, Globe, Ariz; data from R. L. Herrick in 1910 (252). In the following example, width of vein is 7 to 15 ft, averaging 9.5 ft; dip, 58°; footwall is hard and smooth; hanging wall, weak and ill-defined. Levels are 100 ft apart vertically, connected every 100 ft by raises on footwall. Raises are divided by stulls into a 4-ft chute are timbered by heavily lagged sets, 5 ft apart. between back of ore and top of lagging; when 15 ft centers. s; chutes are ndoned when like that at ct, all broken ises, where a ing. Su may be contiguous, or sep pillars, mined later in sa

Fig 300. Gilman Cut and Fill, Plan of Main Level

tinctive feature of the method is that the floor of each stope is trough-s broken ore slides without shoveling to chute gates under middle of stope. Fig 300 shows typical lateral development; level interval is 100 ft; main haulage drift *A*, from which crosscuts *B* are driven, is preferably in wall rock. Raises connect with haulageways on level above; work in raises through country rock is delayed until the waste can be used for filling. STOPING AND FILLING begin at a raise; back of crosscut is shot down and widened as at *C*, Fig 303. Crosscuts are timbered with temporary sets (Fig 301) as soon as the back has been cut out to a height of 8 or 9 ft above rails. The sets are 5 ft apart and floored with 4 by 10-in plank, except for a 12-in space over track, which is covered with 2-ft pieces of 2 by 10-in placed crosswise. A piece of 2 by 6-in plank, spiked to the flooring on each side of the central opening, holds the 2-ft pieces in position. The temporary sets reduce shoveling in early stages of the work. Though only 5 ft high, the sets admit a 30 cu ft-car, for receiving ore falling through the o which is uncovered as required by prying up the short planks. Cutting-o

lling methods (Art 59, 60, 66), essentially for
ls, have a wide and growing range of applica-
oo great for timber, and is the only sure means

STANFORD LIBRARIES

of permanent support of overlying surface or higher orebodies. Where dence is allowable, caving methods (Art 71) are usually cheaper, but ited to certain types of orebody (Art 83). Filling is also employed for or containing much waste that can be sorted in the stopes; waste can be support, and cost of hoisting it avoided. Where timber is costly, fille may be cheapest, and are preferred to timbered stopes even if latter are ad

Other factors governing use of filled stopes: STEEP DIP is desirable; w than 35° to 40° the cost of delivering and distributing filling increases Thick, flat orebodies, minable in rooms of considerable height, are exceptions to this statement (see Calumet & Ariz mine, Art 66). Fin can be handled cheaply on flat dips in a stream of water, but in gene device is better suited to delayed than to contemporaneous filling (s filling, Art 64; note the use of water at Mt Lyell and Calamon mines, Contemporaneous filling is best applied in STRONG ORE, where the ba stand safely, or require only temporary stulls or cribs (Broken Hill Filling is less advantageous in WEAK ORE, because excavations must b much auxiliary timber is usually required, and the close filling often n involves much shoveling. Filled square-set is the type of filled stope in U S for weak ores (Art 46); the crosscut method is an alternative (se for its limitations).

Advantages of filling: (*a*) Walls of stopes are supported permanently, wi danger of "creeps" (Art 55). Filling will settle but little if the material is st carefully placed; fine stuff like mill tailing packs well; weak rock carelessly pla settle as much as 50% under pressure. (*b*) Use of filling avoids risk of fire, alway in timbered stopes. (*c*) When properly applied, filling allows practically extraction of an orebody. (*d*) Ventilation is usually good, through the numero and raises; air currents must travel near working faces and can not short circuit, a stopes. (*e*) Waste from development can be used for filling, thus saving cost of h

Disadvantages of filling: (*a*) Cost of obtaining and handling filling, whic be compared with that of alternative methods of support. (*b*) Cost of gangw chutes. Maintenance of chutes is often difficult; its cost increases with heig and largely determines the maximum economic level interval. (*c*) Some fines when broken ore drops on top of filling. Loss is important where ore is rich a occur in brittle minerals, is greater in coarse than in fine filling, and recurs with layer of filling; hence, total loss of fines in a lift depends on height of stope sli between filling operations. (For prevention or reduction of this loss, see Ex practice, Art 60, 61, and 66; also under Floors, Art 47).

Filled flat-back *vs* filled rill stopes (20, 83, 146, 257, 258, 256). Flat-back s commonest. Factors influencing choice: ORE AND RILLING ARE HANDLED mor in rill stopes, as gravity assists their movement; flat-back requires more chutes a twice as many filling raises (20). Wide rill stopes lose much of this advantage, must be distributed to, and ore shoveled from, sides of stope. SORTING may b flat-back, but not in rill stopes. DELAYS in handling and setting up drills, in in timber and supplies, and time lost by men in reaching working places, are le back than in rill stopes, because the level surface of fill in the former facilitates m of men. Drills must be removed from a rill stope before blasting, but can ge placed in safety in a flat-back stope. SUPPORT. Stulls and cribs may be pla cheaply and efficiently in flat-back stopes; the back may be arched if desired rill stope tends to make its back self-supporting, even if orebodies contain horiz planes of weakness. Fairly firm walls are readily supported in either type walls require close filling, involving much shoveling in flat-back stopes; rill stope filled tightly by gravity. BREAKING GROUND (Art 26–28) is usually underha stopes (compare Sup & Boston mine, Art 66); it must be overhand for close fill stopes. FLEXIBILITY is greater in flat-back stopes; area of stope may be ex any horizon; prospecting openings may be run into walls where desired and produced used for filling; horses of waste or low-grade ore may be left unmined stopes, faces must advance uniformly and excess waste can not be stored. Out a rill stope usually ceases while filling; in a flat-back stope, mining may often p

TY. Principal danger in both types is from falls of utions in flat-back stopes). The sloping fill in rill dged from walls or back (or from surface of fill) near e and injure men; this risk is increased where fill is and CONTAMINATION OF ORE with waste are generally ore fines are lost when ore rolls or slides to chutes in in flat-back stopes. Rill stopes are filled at mini- nds at its angle of repose; but, as ore blasted upon ay cause much filling to roll down into the chutes, l with plank if ore is to be kept clean, or if a large

best employed in steep-dipping veins, less than strong and of uniform character, walls fairly fined. Under other conditions, the advantages weigh their higher cost for handling ore and ce of the factors discussed above varies locally.

KAGE STOPES

68. General

are overhand stopes in which the broken ore completed. As rock increases in bulk when ore in a shrinkage stope must be drawn out as orking space under the back. The remaining s temporary support to walls; it is drawn when y be left empty and allowed to cave, or may be re is called SHRINKAGE STOPING WITH DELAYED -STOPING and OVERHAND STOPING ON ORE are note shrinkage stoping; other names are "lay e mining" (Swedish).

Procedure in wide stopes is similar (see below, and Art 69).

Chutes for shrinkage stopes are sometimes built up at regular intervals
waste-filled stopes (Art 60); they are then used for passing excess ore to the
fill of broken ore in a stope is stable, a weak back may be supported on cribs
Hill (Art 63), but this practice involves much shoveling, which is obviat
shrinkage stopes (Fig 308). Chutes may also be justified by the presence
ore, which can be sorted in stopes and kept separate for special treatment
below). Chutes are sometimes used to handle small patches of waste,
otherwise mix with the ore. Shrinkage stopes with chutes are relatively
for examples, see El Tigre mine (Art 69) and Bib (199).

Development for shrinkage stopes in narrow veins follows gener
down in Art 15. Level interval may be greater than in filled stop
because there are no chutes to maintain. Raises may be far apart,
being opened from a single raise in the middle, or from a raise
Blind oreshoots may even be mined without any raise to level above
and access being obtained through timbered manways at ends of
velopment practice in wide orebodies is largely a question of arrang
for drawing ore economically from the stopes (examples, Art 69).

Shape of stope-face. Both wide and narrow shrinkage stopes
have a flat back, under which, in drawing excess broken ore, it is eas
tain a working space of uniform height than where the back is inclin
lar. The advantages of a level working floor (Art 67) also apply her
shows a stepped-face shrinkage stope.

The shrinkage principle may also be applied in rill stopes of moderate
allow use of down holes, which alone should determine the angle of rill. St

a stope-drift, as indicated by dotted lines; this device secures stron for levels, but is limited to deposits of moderate width; haulagew driven in walls on both sides of stope (Ariz Copper Co, Art 69).

(*e*) Haulageways and chute-gates should be located with refere produced on the surface of broken ore at top of stope by drawing of vertical stopes, 25 to 30 ft wide, the best location for a single row of is in center of stope; if placed along one wall, the surface of broke tends to pitch toward that wall and shoveling or staging is required stope-back on that side for drilling. In inclined stopes, ore tends t on hanging-wall side, regardless of position of drawing points; sor placed on footwall, for drawing off ore there when stope is to be en

J. A. Fulton furnishes following statement as to practice at MELONES MI has a general application (note *D*, Table 30, Art 28). Shrinkage stopes widths of 10, 25, and 40 ft, with dips of 70°, 50°, and 70° respectively. Wi the steep dip are the easiest to keep in shape, as the drawing down of ore is and more easily controlled. With a 50° dip, as ore draws down first on the it is impossible to place holes as advantageously as on 70° dip.

Chute-gates suitable for shrinkage stopes are described in Art 91. BETWEEN GATES should be small, to reduce amount of ore remain them when the stope is finally drawn, as empty stopes are often too d shovelers to enter. Gates are usually 12 to 25 ft apart; use of A-sl (Fig 320) between gates allows larger intervals. Where levels are remaining between gates may be recovered by cutting out lagging a the ore on the level (262).

Access to shrinkage stopes is as follows:

(*a*) Timbered manways are built up through broken ore; in na they are timbered with 2 rows of lagged stulls; cribbed manways wider stopes. For greater security, manways are often placed at en if located elsewhere, cribbed manways should be midway betwe gates, where they are least affected by movement of broken ore duri

At Lake View Consols mine, Kalgoorlie (Fig 309), in steep-dipping stop wide, cribbed manways 2.67 ft square have proved the most satisfactory bering. When located between drawing gates they do not collapse during st ways are abandoned about half way up the lift, raises to the level above th access; level interval is 100 to 200 ft; manways collapse when stope is final many usable timbers are recovered (260).

(*b*) Raises are driven in walls, or in pillars between stopes, and con stopes at vertical intervals of 15 to 30 ft by short drifts. This is com stopes and affords strong protection for traveling and air-ways (se Art 69; also Braden mine, Art 88).

Sorting in shrinkage stopes is not ordinarily feasible. (For exc Cobalt, El Tigre mine, and Republic mine, Art 69.)

Support of back and walls. Shrinkage methods are primarily fo the back will stand unsupported and walls will stand while stope is be (Art 70). For support of the back in shrinkage stopes with chutes, plan, above. Loose slabs in stopes without chutes (Fig 308) may b temporarily by stulls, preferably tapered and set with their big facilitate recovery from above; this is practically the only form feasible during stoping. Occasionally the back and walls of stopes width are timbered while ore is being drawn, to protect men working or to prevent contamination of ore by slabs from walls (Ariz Copper

grade streak is then broken with light shots, the ore being sorted, sacked, and to smelter. The remaining low-grade ore on opposite side is then broken (co Resuing, Art 61). At some mines no sorting is done in stopes. At NIPIS levels are timbered with 3-piece sets; raises to level above are used as manway is a section through 2 levels of CONIAGAS MINE, showing method of dealing wit with so flat a pitch that ore will not run along the floor by gravity. Chutes, ra funneled tops, are put up from the level through barren material; they per of the surface of broken ore during stoping and of the final withdrawal of ore.

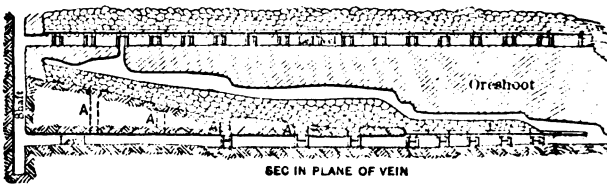

Fig 315. Shrinkage Stope, Coniagas Mine, Cobalt, Ont

El Tigre mine, Sonora, Mex. Data from R. L. Herrick in 1909 (266). ores occur in long shoots in 4 to 7-ft veins, dipping 70 to 75°; wall rocks ar veins carry 4 to 30-in streaks of high-grade smelting ore. Level interval, 100 topography is rough and all levels are drift-tunnels. Mining is done in shrink with chutes 25 ft apart; every 4th chute has a manway compartment. Leve bered with lagged stulls. In stoping, the high-grade streak is first stripped blasting down waste and mill ore alongside; it is shot down on next shift, sor canvas, and sorted out and shoveled into chutes. Enough mill ore is draw chute-gates to keep a proper working space below the back.

Kalgoorlie, W Australia (258). See Art 66 for ore occurrence. Where wa are strong enough to permit, rill shrinkage stopes (Fig 309) are used. Levels, ft apart, are timbered like filled rill stopes (Art 66); chute-gates are built int timbering every 20 ft. Economic length of stulls for levels (set as in Fig 164, 14 to 18 ft; on greater widths, saddle-back stulls have been tried and found unsa At LAKE VIEW CONSOLS MINE, in lodes up to 35 ft wide, it proved advantageou levels 12 to 13 ft wide and to widen the stope to the walls directly above them level was then protected by horiz stulls of moderate length, resting in hitches cu section of stope floor with top of drift. At GREAT FINGALL MINE, with a 2 interval, simple stulls failed on widths over 18 ft. Horiz stulls, reinforced (Art 36), were the cheapest and best means of protecting levels at widths of 1 stulls were 15 to 27 in diam, set 5 ft apart; 1 post was always placed near ea a stull, with intermediate posts as required (260). Only 1 raise in center of h mined is required for preliminary development. Slope of stope faces, 23°; all are water holes. A manway 3 ft sq, carried up at each end of stope, is cribbed round timbers halved at corners; manways are halfway between 2 chute-gates are filled after ore is drawn.

Tomboy mine, Telluride, Colo. Orebody is a gold-quartz fissure, 1 to 1 (normally 4 to 7 ft); dip, 77°; country rocks, andesite and breccias. Shrinka are similar to those in Fig 308, Art 68, but ore pillars are used to protect levels timber. Swell of broken ore is 33%; chute raises are 20 to 25 ft apart. I finally cleared of track, timber and pipes, and the pillar above shot down before below holes through (269).

Cresson mine, Cripple Cr, Colo. Data from R. L. Herrick in 1911 (151). rock is granite; gold telluride ores occur either in massive shoots in fissured zo replacement veins in well defined sheeted zones alongside of or near basic dikes. is done in flat-back shrinkage stopes, details of work being varied to suit size, sh richness of ore; swell of broken ore, 30% to 35%; for data on breaking ground Table 30, Art 28. Levels are usually opened by drifting along one wall of ore its full length; then crosscuts are driven to the opposite wall to determine ir in width and to allow sampling. Level-pillars are left in low-grade ore on width 10 ft; height of pillar = width of orebody. Lagged stulls (Art 36) are used

16 ft. Stulls and posts, spaced 6 to 8 ft apart, are
are 14 to 16-in diam, set horizontally and made by
d joint; posts are 9 ft long. This timbering is strong

te-gates. Open square-sets, which were inadequate
had reached some height, were strengthened by lag-
ging the sides of certain sets and then fill-
ing them with ore by shooting down the
lagging overhead; sets behind chute-gates
were left open for access in making repairs.
Level timbering and tracks were all recov-
ered after stopes were drawn, starting at
one end of stope and retreating toward
the other. Flat-back shrinkage stopes
were used. As soon as any part of the
back reached a point 8 ft below floor of
level above, it was caught up on cribs,
wedged tight and in places filled with ore.
Level-pillars were mined as in Fig 317;
work began by drilling holes in back around
a crib in middle of stope; the crib was then
removed and the holes blasted, making an
opening about 12 ft diam into the stope
above. Work then stopped for several
days to allow loosened rock to work and
drop; then the back around the opening
was attacked. Cribs were close enough
together to allow all holes to be drilled un-
der their protection. After center opening
had reached a diam of 30 ft, the remaining
pillar sagged and its wt was supported en-
tirely by the cribs; this wt and the result-
ing incipient fractures materially reduced
consumption of explosive for mining rest
of pillar. This method is stated to be safe
labor and dynamite, as compared with the drilling
ar and shooting them simultaneously. In one place
ied to a height of 320 ft. This saved cost of mining
fairly soft and required thick pillars, would have had
was drawn from this stope on several levels through
the walls.

d up as a shrinkage stope, about 40% of the ore oveling. Stoping could be done simultaneously l-pillars were left at top of stopes. Level-pillars ve were finished and drawn. The only timber ways. This general plan has been used on vein nsverse stopes are carried, separated by pillars. ls are opened by driving main haulageways *H*, sscuts are turned off at intervals of 102 ft and on center lines of pillars, which are 42 ft wide; 'breakthroughs") are run each way from cross- occasional raises are put up for ventilation. A ried over entire sill-floor; where deposit is very neat hanging wall. At ends of breakthroughs open cribs covered with sheet steel, just high s; tops of breakthroughs are enlarged at stope ope is then carried up as a flat-back shrinkage stope above, about 20 ft thick at crown. The g in breakthroughs; miners enter stope through ways *K*. BREAKING GROUND. Breast holes are as much ore as possible with each blast; block- an fine breaking from face. DRAWING STOPES. he end and is followed closely by filling (see sec area of walls left unsupported while ore is being ome useless they are removed; track is laid into ille; ground is so strong that men may work in Empty stope floors are covered with a mat of l with timber for a height of 15 or 20 ft before n an opencut or from old workings above, and cting with crosscuts in the pillars on level above, rom *X* may enter stope through the level-pillar, *CD*, Fig 327). MINING PILLARS. After stopes then the pillars between stopes; all are removed ts (Art 45). GENERAL. As a whole, the above ed method (Art 84), involving both shrinkage ed here for comparison with Alaska-Treadwell alternative methods for similar orebodies.

, Shrinkage Stopes

tage methods is limited by their rigid require- haracter of orebody and its walls. These are uiring little timber and practically no shovel- wards low costs. Under proper conditions, narrow or wide veins; as auxiliaries to other ion to large, massive orebodies (Art 84–89).

nkage stopes without chutes (ore-passes); their us if read in connection with the limitations of discussion is based largely on a summary by see Bib (83, 132, 260, 274).

lication of shrinkage methods: (*a*) Dip of 60°, for ore to settle freely; tendency of nging-wall side decreases as dip steepens. ape, otherwise loose ore will lodge on foot- s are usually too dangerous for shovelers ay be timbered during drawing (Art 68), ility of using open stulled stopes (Art 36, t to mine in shrinkage stopes, even if in ; sudden flattening of a shoot necessitates ises through unpayable ground (see Conia-

STANFORD LIBRARIES

gas mine, Fig 315, Art 69). Regular and fairly continuous orebo essential, because with shrinkage methods stoping must be carried ably in advance of output requirements. (*c*) Ore should be stron stand over back of stope, occasional slabs being supported by stu of weak ground may be broken underhand (Ariz Copper Co, Art 6 sistently weak ore can not be mined in shrinkage stopes. (*d*) Ide should be of uniform value; at least it should be payable throughou of waste can not be left unbroken, and sorting in stopes is rarely f exceptional conditions at Cobalt, and at El Tigre and Republic mi (*e*) Walls should stand without crushing or spalling off into the brok stopes are drawn. Friction between ore and walls during drawi any natural tendency of walls to slab off; the hanging wall especial strong. (*f*) Prospecting openings cannot be run in the walls of shrin hence limits of orebody should be well defined. (*g*) Physical or n peculiarities of ore may prohibit shrinkage stoping.

Some broken ores tend to "pack" in stopes, and must be blasted out; o occurs only when stopes are left undrawn for a considerable time; freq prevents packing. Packing may be due to pressure or to cementing action o on pyritic ores; it may be controlled if the size of stopes and the plan of regulated for drawing stopes promptly. At Coronado mine, Ariz (Art 69) the considerable pyrite. Broken ore when drawn was found to be highly oxi caused trouble in concentration and led to abandonment of shrinkage meth

Advantages of shrinkage stopes: (*a*) Raises and levels may be far apart, t cost of development. (*b*) No shoveling of ore is required in working spa stope; if ore can be drawn through chute-gates, there is no shoveling (se conditions justifying shoveling in drawing off ore). (*c*) Little timber is u for miners and shoveling plats are unnecessary; timber for manways is rec stope is drawn. (*d*) Ventilation is good, as air currents follow working face pared with filled stopes, shrinkage stopes sometimes wholly save cost of fil event, filling an empty stope in one operation is always cheaper than conte filling (Art 59). Shrinkage stopes also avoid loss of fines in filling, and cost and of shoveling ore to them. (*f*) In narrow veins, shrinkage stopes c stulled stopes (Art 36, 37), and are preferable to the latter for wide veins and They furnish a firm working floor for miners; timber staging may reduce causing a feeling of insecurity. (See Art 43 for comparison with sub-level st

Disadvantages of shrinkage stopes: (*a*) If chute-gates are used, fine br quired; some large pieces may be buried in broken ore, and make trouble in and gates. For alternative mode of dealing with this problem see Arran protecting levels, Art 68. (*b*) Some spalling of waste from walls into ore alw a given amount of it reduces the aver value of broken ore more in narrow t stopes. Much ore is lost if walls crush. (*c*) Ore can not be selected from di faces, for maintaining a uniform grade. (*d*) Ore left in stopes until they are up a considerable investment for labor, explosives, etc, to break it, and ad capital is necessary. At a given mine, the tonnage of broken ore eventual fairly constant maximum. Interest on money required to break this to operating charge against shrinkage methods; it represents the cost of utili ore for support. B. C. Yates states that, in 1904, over 1 000 000 tons of brok in stopes at Homestake mine (104). H. C. Hoover cites an example where tons annual production, the interest (5%) on the capital represented by amounts to 7¢ per ton treated (20). A large reserve of broken ore is adva insuring a regular output; but, only the ore in completed stopes is availa purpose. In the few Lake Superior iron mines using shrinkage stopes, feature may be availed of to save cost of stock-piling and reloading from 60 the ore mined while navigation is closed. (*e*) Shrinkage systems are not flexi once started, they are difficult to alter, owing to lack of frequent raises; this true if filling is the only alternative. Change of method may be required b dip, or in character of ore or walls in depth. (*f*) Walls of shrinkage stopes can for lower-grade ore only when stopes are filled promptly and filling is left u walls often crush when filling is drawn down for use in lower stopes.

G METHODS

ose in which ore is first undercut and then
by weight of overlying rock, or by a combina-
custom, operations involving caving of the
ystematic and essential part of the work, are
gh practically all the ore is broken by drilling
ods, SUB-LEVEL CAVING, BLOCK-CAVING, and
ification, each having many modifications.

lled "Slicing."

asses, or thick beds of soft ore, where clean
sired and where the overlying surface need
s and conditions, see Art 75.

General plan. Ore is mined in a series of horiz floors or slices, taken in descending order, from the top of the deposit. Each floor is mined in small sections, the roof of each section being allowed or forced to cave before an adjacent one is attacked. Work on each floor retreats from limits of ore toward points of entry; all of the ore is broken by blasting. The principle is illustrated by

STANFORD LIBRARIES

where single drift-sets would require posts of unmanageable length and drift-sets would not support the side pressure of caved ground (Art 72). Pr stulls) are employed where floors are laid on sills, the latter taking the place a drift-set. Props are also used in slicing under rock capping at top of an under peculiar conditions in Minnesota iron mines (Art 72). For light pressur (Fig 350, Art 74) form cheap and satisfactory supports for plank floors laid See Art 72–74 for details of timbering.

Floors may be of lagging (Fig 328) or plank. Plank is best, bec be laid with tight joints to keep out fine waste; it is also easier to block up from below than round lagging. Usually, one layer of 2 by 12 plank, in 10 to 16-ft lengths, makes a good floor; double layers ma in a few slices at top of orebody; on Mesabi Range, single layers of have been found adequate (Art 72).

Sills under plank floors are generally omitted. To avoid breakage, the pla directly on ore, hence sills must be sunk in the floor, as in Fig 348, Art grooves for sills is slow and costly work, and, as it is practically impossible t on successive sub-levels directly under one another, there may be trouble i sills from below. Sills allow use of props instead of drift-sets in slices, but compensating advantage, as it effects no material saving in timber. Th omission of floors on certain sub-levels is possible only under a thick mat feasible in high-grade ore. Data as to this are conflicting. It is successfu at Cananea, it increased costs in spite of saving timber (Art 74).

Handling timber. In top-slicing, as in Fig 328, all timber for slic hoisted up the ladderways of raises; small air-hoists of the stretcher-ba 15, Art 21) are commonly used for this purpose. See Art 72 and Caspia 73) for modes of arranging work so that timbers may be lowered to

Blasting down timbers in slices to force mat to cave is done by sir firing of small charges of dynamite in holes bored in the posts. Holes near the middle of posts, and are 4 to 6 in deep; in large-scale work, can be saved by having 1 or 2 men bore all holes with air-driven aug a stick of dynamite or less is used per post; it is often unnecessary the posts in a slice (see Fig 338, also Caspian mine, Art 73).

Some engineers hold that mat settles in better shape if the supporting allowed to fail by pressure than if they are blasted down; some blasting is alwa Top-slicing is possible only when the mat caves promptly and rests solidly on this condition is apt to be met when posts in slices are shot down. For har areas of mat which "hang up," see Morenci-Metcalf district, Art 74.

Recovery of timber is rarely attempted in top-slicing, largely because che used, which will not stand removal and reuse. But, possibilities of salvage a by following statement from P. B. Scotland, Gen Supt Ariz Copper Co, Morer

"In mining coal by longwall method (Art 108), 25 to 50% of the stulls support are recovered. When mat becomes thicker in our top-slice stopes, a similar sa be made. At present, the mat is often penetrated and broken by vertical st would not occur if they were removed. In longwall working, it is . . . . more to timber closely and make large recovery of stulls than to reduce the number and lose all of them."

Height of slices. (*a*) Height of drift-slices and of those where sills c above are picked up on stulls is limited by max length of post whi handled; this is determined partly by size of openings through whic must pass and partly by comparative costs of handling and erecting different lengths. Usual height of drift-slices is 10 to 12 ft (Table 4 represents an economic mean of all the factors. Art 72 gives exampl drift- and prop-slices, and reasons for their use. (*b*) In very heavy height of slice is generally reduced to avoid need for heavier posts, w more to handle and often more per bd ft than the 6 to 10-in diam comm

swinging" under heavy pressure (Bingham, fluences possible height of slices. Square-set lices 17 to 20 ft high are sometimes timbered . is thrown back and becomes a part of the mat; ing systematic underground sorting.

begin directly at the top of orebodies overlain re necessary, to advance sub-levels or slices. and costly, and causes unavoidable mixture which may be cheaper in spite of the ore ft below top of orebody. Pillars thus left level, and aid in holding back fine waste dur- ian mine, Art 73; also Mesabi practice where , Art 72).

ng orebodies overlain by a ROCK CAPPING; re often irregular. It is then essential that g up over large areas, which may give way flat surface under which to begin slicing is ps of orebodies are usually mined as open ng are examples of practice (see also Mesabi 52, Art 74).

nci, Ariz (Art 74), tops of highest raises are con- ich an open square-set stope, usually 10 to 20 ft

STANFORD LIBRARIES

high, is carried to capping. Stringers of ore extending into capping are fo which also weaken the back. Stope floor is covered with 2 layers of 2-i angles to each other. Deep uppers are drilled at frequent intervals in holes are also drilled in posts of square-sets; all holes are blasted simult

At Ariz Copper Co's mines, "tops of orebodies are mined by open st stopes, or sub-level caving (Art 76). A double floor of 2-in plank is laid caved either to surface or sufficiently high to make it safe to work under

At Cananea, Mex (Art 74), tops of orebodies are mined with square-s of 2-in plank laid on 5 by 10-in sills, 10 ft long. Capping sometimes sta to allow salvage of some timber. When capping hangs up, sets are no but are filled with waste to form a cushion above the mat on which larg without endangering work in the slices below (282).

In this work a continuous square-set stope over whole area of ore essary. As 1 or 2 floors of caved sets sufficiently protect the slices height are opened at different elevations in different parts of the quired by irregularities in lower surface of capping. This avoids h stopes of large area, and does not interfere with slicing. Where co ore and capping is regular, simpler methods of starting a mat ar capping is very soft, slicing begins at top of orebody, usually with d first few sub-levels to build up mat quickly. In harder ground, a br 10 ft high is carried across top of deposit, with stulls and headboa the back. After laying a floor, the timbers are shot down. The fo tions are also preliminary to other caving methods in which we ground above the workings is an essential.

Ventilation is generally poor in top-slicing unless fans are used. Sl "dead ends;" decaying timbers in mat give off heat and some CO. F artificial ventilation, see Miami, Cumberland-Ely, and Bingham, Art 74; installation of blowers caused a marked increase in efficiency of labor (28

Percentage extraction by top-slicing is high; usually only 5 to 10 ore is lost. Further details of top-slicing are given in Art 72–74.

72. Top-slicing, Mesabi Range, Minn

General. Mesabi orebodies are flat, or slightly dipping, thick beds of h ing large areas. They are overlain by taconite or slate and glacial drift, or Ore varies in character, even in the same mine; usually it is readily dri augers, but is compact enough to stand untimbered in small drifts for sever of it is hard. Open-cut mining is done where possible (Art 97).

Underground mining, all by top-slicing, is confined to small or deep de would not pay to strip. Examples of typical conditions for underground mi mine, near Hibbing, is a 40-acre tract (the usual area worked by 1 mine 60 ft thick, averaging 40 ft, and underlies the whole tract; shaft is vertic estimated tonnage, 4 to 5 million tons. WHITESIDE mine, near Ruhl, has underlain by ore from 45 to 200 ft thick; depth of overburden, 50 to 125 tonnage, 5 to 6 million tons. Following notes are based on data publishe 1913 by C. E. van Barneveld (35); W. Bayliss, E. D. McNeil, and J. S L. D. Davenport (276); A. L. Gerry (277). For modes of prospecting an and information on ore occurrence, see Art 11, 12.

Development. Usual ENTRY is by a 3-compartment hoisting shaft, sun part of deposit to facilitate drainage (Art 17). Shafts generally penetra a location in country rock is preferable. From 2 to 4 timber shafts are sun geous points, the number depending on area of property; the first (Timb Fig 329) is sunk near hoisting shaft and at same time. Timber shafts are 6 9 ft in section, and contain a ladderway. A MAIN LEVEL for haulage is ope of deposit, which usually contains one or more troughs of deep ore. M follow the troughs, their best position being determined from a contour m of orebody based upon borehole data (Art 12). Drifts should be near bott yet kept in ore to avoid more costly rock excavation; to minimize hand sub-levels above, they should extend if possible throughout length of prop

ctors; in deposits 50 ft thick or more, it is good
height that it will extend a considerable distance
and later to drive another and lower main level.

the ore limits, or at property lines, and retreats toward raises. Details vary with height of ore over the sub-level and with character and shape of back. Following are variations:

e of Deposit, Mesabi

Drift-slicing. Fig 330 shows method of slicing at edge or "shore line" of deposit; 3 by 3-ft test raises *R* are first put up at 50-ft intervals, to determine height of ore over the sub-level. At a point *C*, where ore is about 7 ft high,

eight of ore; first slice *EF* is then taken. Cross-
ts, with 7-ft caps and vertical posts of a length

STANFORD LIBRARIES

to suit height of ore. Slice *EF* is advanced until ore becomes too thin to work; p
sets are usually 24 to 30 in. Other slices are driven alongside (see dotted line
shoveled or wheeled to a car in crosscut *DE*. As the rock at shore line usuall
steep angle, it does not pay to turn the trac
slice. For this kind of work, sets are best p
their caps along the sides of *DE*, instead of ac
330). Though slicing may be started direct
sub-level drift, a distinct gain results from dri
liminary crosscut, and slicing up the slope of t
rock; ore comes down grade, posts of slice-s
about equal length, and the whole layout is
ible. When ground in slices becomes heavy
bers are shot down and new slices started alo
ground to right of *DE* is thus mined and caved
shows drift-slicing alongside of caved ground

boards and the pillar *X* is mined; a little sand may run in from adjoining cave
no harm. Sets 13, 12, and 11 are mined next in the order named, and the sides
to 11 against solid ore are boarded with horiz 1-in boards spiked to posts. Sets
opposite side of sub-level drift are then mined, and finally
set 10, which thus far has served as a pillar to protect the
entrance to slices. This work forms a room 2 sets wide by
50 ft long, known as a double slice. The order in which
sets are taken varies widely. Under a strong back, or with
solid ore on both sides, rooms are mined 2 sets wide in one
operation; where caving had not completely filled the pre-
ceding room, sets 10 to 16 would be taken first, and then
sets 9 back to 3. Ground under dangerous overburden,
such as that containing quicksand, is mined in slices 1 set
wide. The reason for slicing from sub-level drift 40 ft one
way and only 10 ft the other is that each room then requires
but 1 curved section of rails. Ore from sets 17 to 20 is
shoveled to a car in the sub-level drift. When a room is
finished, it is cleaned out and its sides against solid ore are
boarded up; if there is ore below, the floor is covered with
a layer of 1-in boards; posts in center and on cave side of
room are then blasted down. Entrance of sub-level drift
into the room is also boarded up (Fig 332), leaving a door
as an exit for the miner who shoots down the timbers, and
for entrance if it is necessary to blast the side of the old
cave to make the room fill. As rooms usually fill quickly

slices simplify this work. Slicing may
taneously on 2 sub-levels, provided work
is at least 50 ft ahead of that below, but
opened before they are needed are often badly crushed when the sub-level ah
and require much extra timbering.

Prop-slicing. Extensive areas occur where ore is overlain by a consider
of firm taconite; the slice at top of deposit can then be taken out with p
required; max length of prop, 20 ft. Some orebodies 5 to 18 ft thick lie be
of taconite, the roof layer being 40 to 50 ft thick, very hard and tough an
when a large area is mined out. Such ground is developed by a main haul
which drifts are run 50 ft apart to the "shore line;" the pillars are then re
slices. Drifts are timbered with 3-piece sets; slices, with 10 to 18-in props
ft apart on cave side of slice. Where height of ore exceeds 12 ft, 1 floor of
erected and 2 props are set on each cap. This form of prop-slice is an open
it gives cheap ore and leaves large rooms which are not caved unless the ro
the roof comes in large blocks when it caves.

Variations and combinations of foregoing methods, to suit local condition
ideas, have had a limited use; thus, TOP-SET SLICING is a mode of timberi
with 2 tiers of drift-sets, one above the other (278).

Handling ore. Usual tramming distances on sub-levels to the raises ar
electric or mule haulage is used on main levels; irregularities in the bedro
transfers necessary.

Extraction by these methods is high if work is done carefully, keeping
clean, trimming the back and catching all ore on sides; it is from 95% to

ation sets of 12 by 12 timber with 9 or 10-ft posts her protected by timber bulkheads 10 ft high; two bulkheads are 7 by 7 ft and two 7 by 11 ft in plan, as shown. Drifts *A*, *B*, and *C*, usually untimbered at first, are run in the order named. Slicing begins at ends of *B* and *C*; Fig 349 shows 4 successive stages of work in same block. New slices are started as soon as those alongside have advanced a few ft. As many men as can work to advantage are put on; ore is mined with greatest possible speed, until only 4 central pillars around the supply raise remain (see 3rd stage). Inclined raises *F* are then put up to about the middle of each pillar; crosscuts (not shown) are driven to raises *F* from drifts *A* and *C*; slicing then continues, working from outside of pillars back to bulkheads, which by this time have squeezed down to a height of 4 to 6 ft. On completing this work, the last of the stope is caved; it is found best to let ground settle several weeks before starting another floor. Slices are 10 ft high, timbered, according to the ground, either with single sets, of 2 8-ft posts and a 12-ft cap, or with double sets, of 3 8-ft posts and 2 7-ft caps, all round timber. No floor is laid if mat is thick enough to prevent runs of capping; elsewhere a 2-in floor is spiked to 2 by 10-in sills; 5 by 10 and 4 by 8

sills were tried, but seemed to be no stronger than 2 by 10-in, after subje and pressure of a completed slice. Bulkheads of old timber are built wi aid slice sets; the posts are shot down as soon as possible. All drillin drills, using a water spray. Ore in slices is shoveled to raises or handled i method has given good results; weight on timbers does not get beyond c time that slices must be kept open. It has been found that pressure on not intensified by caving around them. But ore in pillars is fractured, the only holes needed to break it. This fact, combined with the handli vided by raises *F*, makes pillar-ore cost less than that from outside slice of the blocks is important; without it the heat from mat is excessive ciency of labor. Air from a 60 000-cu ft fan is taken to the sub-level floor and forced through raises into the slices as desired. Costs. As sh the production per shoveler is 20 tons and per total man-shift, 10 tons, t about double those obtained in slicing on long faces without artificial ve

Bingham, Utah. Data from D. W. Jessup in 1914 (66). Top-slicing mining lenticular replacement deposits of pyrite, galena, sphalerite, a occurring wholly in limestone or along contacts with a quartzite footwall. soft; hanging wall is very heavy; lenses vary from a pinch to 100 ft about 65° and may be several hundred ft long. Some mines use square cases, top-slicing was adopted after square-set stopes had collapsed or pr because of excessive reinforcement required. Distinctive feature of to here is the use of square-sets for slices, locally called the SLASH SYSTEM. of a typical orebody is shown in Fig 95, Art 15. Entry is by tunnels or level is driven in footwall at bottom of lens, with crosscuts underneath o at intervals of 75 to 100 ft. Similar levels, 100 ft apart, are opened abov by Fig 95, the longitudinal drifts on levels No 1 and 2 were driven in o lens. Square-set, 2-compartment raises are put up between levels an they are best located in ore, but the shape of the deposits requires much Raises are kept away from heavy ground on hanging wall and are offset to break the fall of ore, prevent its packing in chutes and reduce wear c Raises in ore are about 50 ft apart; when mostly in waste, they are 100 f

sets of chute in each raise 2 floors of gangway-sets *m* are carried across th a third is started. Besides the above work, crosscuts are sometimes drive tervals from the haulage drift, and raises put up from them on 40-ft cent

Slicing. Fig 351 shows slicing after work is well started; Fig 352 is a timbering in successive slices. Top of orebody is mined on square-sets, st.a wall and retreating toward raises; posts of sets rest on ore without sills As work progresses, a 2-in floor is laid on 4 by 10 sills *a*; posts are shot dc least 2 open sets next to Usually 1 floor of square-sets even off the stope back; so back does not cave promptly filled to form a cushion ov Ground along gangway-sets square-set slice is cut back and a floor laid there on slopi long; the ends of horiz sills to fit under sills *b*; both sill pieces of 2-in plank placed joint. A second slice may b of block, as soon as the cave comes to rest. Work begi gangway-set; a slice-drift, 8 6 ft wide, is driven on a 45° sl to lay 11-ft angle sills *b*; t carried horizontally to the c Sills of floor above are picke

Fig 352. Mitchell Top-slicing. Diagram of Timbering (letters refer to Fig 351)

6 to 8 in diam. This slice is completed by driving contiguous drifts; usual space is kept open next to the working face; stulls in third row back from begin to crush as the face is being drilled (Sec *DD*, Fig 351); stulls are s necessary. This procedure is repeated for lower slices, which vary in heigh of angle-sills used (Fig 352). In each slice, a 2-in floor is laid on 4 by 10 sills Max feasible height of slice, 10.5 ft, is not attempted until the fourth slice the mat is under perfect control. High slices reduce shoveling, as the slides in them can be made longer. Bulkheads *e* take the weight of mat off the gangway-sets, the posts of which are cut below bulkheads at *k*. Ordinarily, bulkheads built in second slice and in every third slice below will prevent gangway-sets from crushing; in other slices, sets are braced with stulls (Fig 352). Enough partly crushed timber comes from the mat to build bulkheads. BREAKING GROUND. Holes, made by 2.25-in piston-drills on columns, are usually located as in Fig 352. Weight of mat aids breaking, and cut-holes and lifters generally suffice. It is rarely necessary to set up drills in inclined parts of the slice-drifts; this ground is broken by drills mounted in gangway-sets and at top of the slide. HANDLING ORE. From 67 to 80% of the ore broken in a slice falls on sloping floors, or is thrown there by blastin gangway-sets; the rest is shoveled. As slicing proceeds downward, the gangway-sets are extended, but they cannot be opened far in advance of slic weight on them is considerable even when bulkheads are used. Grizzlies gangway sets at foot of the slice-slides; below these, 2-in plank slides *i* are la Fig 351). For the upper slices, slides *i* connect with chute compartment *g* chute-gates are erected in sill-floor gangway-sets for loading cars (section *A A* ore extends below the haulageway, raises are put up from a lower level and

uire much reinforcement, it saves timber; elsewhere
ber than square-sets. But, cheap grades of timber
er framing, and its erection in stopes takes less time
d) Rich fines are recovered in slice below; some fines

STANFORD LIBRARIES

are always lost in filled square-set stopes (Art 47). (*e*) More unskilled l employed; more shovelers and fewer timbermen are needed. (*f*) Stoping m porarily, with a lower cost for renewing or reinforcing timbers.

Relative disadvantages of top-slicing, besides the general disadvantages s are: (*a*) it is less flexible; (*b*) ground is broken by breast stoping, which more than overhand work; (*c*) a much greater footage of drifts, raises, etc. is a given block of ore, and this delays production from any area; (*d*) mining i top of orebody; stopes cannot be opened on lower levels; hence, top-slicing of small area may not produce the desired output; (*e*) cost of bringing tim stopes is usually higher in top-slicing than in square-setting (Art 47). Sub- is the usual alternative caving method (for comparison, see Art 79).

76. Sub-level Caving

General. Sub-level caving, a logical development of top-slicing (Art 71 used on the Lake Superior Iron Ranges, but rarely elsewhere in the U S. terms are: SUB-DRIFT CAVING, SUB-LEVEL SLICING, SUB-SLICING, SUBBING, S CAVING and TOP-SLICING WITH PARTIAL ORE-CAVING (see Art 71).

Suitable orebodies are wide deposits of moderately soft or mode ore, overlain by ground which will cave readily. For limitations an ments of the method, see Art 79.

General plan. As shown by Fig 353, the method resembles top-slic a timber mat forms over the workings, and ore is mined in horiz slice descending order. MAIN LEVELS consist of drifts *D* and crosscuts *C*, planned to facilitate haulage and for proper spacing of raises *R*. SUB-LEVELS ("subs"), opened from raises as needed, are usually 15 to 18 ft apart vertically, and consist of timbered drifts *S* and crosscuts *T*, cutting the ore into pillars (Fig 360, 363, Art 77). This development work leaves pillars *P*, 7 to 9 ft thick, between the back of one sub-level and floor of that above.

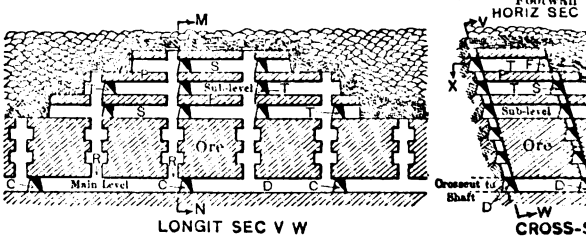

Fig 353. Sub-level Caving in Wide Vein (diagrammatic)

Mining begins on the highest sub-level, the end pillars being attac work retreats toward some central point, as in the longit sec *VW*, Work on individual pillars may begin at the hanging wall and retrea footwall (cross-sec *MN*), or may retreat from both hanging and foot t middle of vein, or may retreat in a direction parallel to the strike. In a slice-drift or slice *FF* is driven from crosscut *T*, next to caved ground way across adjacent pillars; it is timbered with drift-sets and floo lagging or plank. The overlying ore is caved into the slice-drift in smal from points *F* (horiz sec *XY*), and retreats to crosscut *T*. Ore is sho barrows or small cars and trammed to raises. Contiguous slices are su driven and caved until the footwall is reached. The caving of ore o

; stripping would then begin at inner end of slice.
ce-sets holds back the gob while slice-drifts are
ws a method permitting CLOSE CONTROL of both
eral and vertical pressure. A slice-drift *AA* is
ven as shown, leaving a 6 or 8-ft pillar of ore *PP*
t to gob. Work of removing pillar and stripping
slice begins at *A* and proceeds as follows: cross-
s 1 are driven through pillar *PP* and ore over 1 is
ved; ore over 2 is then caved, and crosscuts 3 are
ven and stripped; then ore over 4 is caved and
on. The back of sub-level crosscut *C*, at 10, is
ipped last; the next slice-drift is driven at *FF* and
ocess is repeated. On the GOGEBIC RANGE, Mich,
lars only 3 ft thick are sometimes left between
ce-drifts; they are drawn without system when
drift is stripped (297).

Fig 357 shows work in STRONGER GROUND under a
ong mat. Drift *A* is a sub-level at end of ore-
dy; slice-drifts *B* and *C* are driven in turn along-
e of it. By the time slice *B* is completed, or
ssibly not until slice *C* is started, timbers in *A*
gin to crush. If ore overlying *A* does not come
wn, timbers at far end of *A* are shot out, and cav-
g is begun there by blasting down the back with
ht charges. The ideal condition is to have caving
rt at end of *A* and progress steadily back to cross-
t *D*; to accomplish this, some slice-sets may be
nforced and others shot down; similarly, some
rts of the back may require blasting and others
t. Ore caving into slice *A* is loaded by men who
rk mostly under protection of timbers in *B*.
oken timbers are thrown back and become part
the mat; slightly damaged timber may be used

STANFORD LIBRARIES

Sometimes work is planned so that the weight of gob will crush part of th level pillars. Fig 358 shows this method at CHANDLER mine, Ely, Minn (s description of orebody). Stripping on any sub-level retreats from the ends o Drifts *D* cut ore on the sub-levels into pillars say 10 ft square. Weight ground above breaks down ore in the back, and splinters the pillars so that mined with pick and bar, without blasting. Where necessary, long props boards support the rarily, as at *C*. I contiguous slice-drif as in Fig 357 (287).

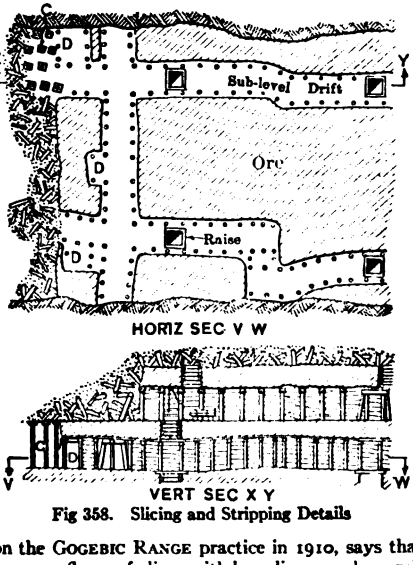

Fig 358. Slicing and Stripping Details

Breaking grou drifts is similar to slicing (Art 71), there is no free fac slicers like those in driven as ordinary 21). Normally, f 60% of the ore p sub-level caving is pressure of the c burden, without us sives.

Timbering. C is used for same re top-slicing. Simp 3-piece sets are ne employed for slices 53 and examples in When slicing und mat, FLOORS are oft P. S. Williams, c on the GOGEBIC RANGE practice in 1910, says that there is a growin to cover floors of slices with boards, even where gob is compact enough good extraction without them. Use of floor-boards sets a definite lin to work to in stripping and helps to prevent mixing waste with ore (27 LING TIMBER. Much timber used in slicing must be hoisted up raises slicing. Where sub-levels are developed in advance of mining require bers for sub-level drifts and crosscuts can be lowered from main l When a pillar of ore is left opposite a hoisting shaft in the footwall, be maintained in the pillar through which timber for both development is lowered to sub-levels(270). SALVAGE OF TIMBER is not feasible.

Handling ore. All ore broken must be shoveled. Barrows, or c 0.5 to 1.5 ton, are used on sub-levels. Some direct shoveling to raises (see Art 71 for comparison). Small amounts of waste can be sorted o in the slices; floors should be laid where this is done, otherwise, the s will appear when slice below is stripped. Extensive sorting is not fe

Mat is started at top of orebody by one of the methods described in Art Fig 361, Art 77, and accompanying text.

Ventilation problems in sub-level caving are like those in top-slicing. mining, powder smoke, and the heat and gases from decaying timber in gob, mu from the working places. Doors and brattices (Sec 14, Art 6) are used to con air currents; working places which can not be thus ventilated have motor-driv fans. Sub-levels are kept connected with main level above as long as possibl tate handling timber; these connections and those with the timber-raises in

Walls near ore are soft; ore requires machine-drills for driving developmen (Table 53). Fig 364 shows main level development (see remarks on oblique 76). Raises, about 50 ft apart and incline deposit, are put up from crosscuts; they are have a chute-gate every 50 ft vertically. The is thus broken, so that men need not descend 50 ft during blasting in stopes. A break in partment is desirable because of large level i also allows one grade of ore to be dumped part of raise, while another grade is being below, thus avoiding delays. Sub-levels are the first being 18 ft above main level. Ore i sections, rarely more than 50 ft square, around (see dotted lines in the plan, Fig 364). Chandler mine, Vermilion Range, Minn (153, 183, 287). Orebody occurs dipping trough (Fig 92, Art 15) capped by jasper. Ore is hard hematite, though and broken, and machine-drills are often needed in driving main levels. Fig mode of entry and position of levels and subs (see also Table 53). Down to main levels were 50 to 75 ft apart; sub-levels, 12.5 to 15 ft apart. Ore in the trough was about 70 ft thick; main levels usually comprised 2 drifts, near the connected at intervals by crosscuts. Raises were spaced 50 ft apart along dri levels were opened, sliced and stripped, as described in text accompanying Fig 3 Sets in sub- and main-levels were 3 to 4 ft apart; top lagging was used in all dr side lagging was needed. No floors were laid in slices. Barrows or small cars were used on sub-levels. Below the 8th level, shaft stations were cut at 20- intervals; intermediate levels were of same size as main levels (Fig 92). Ore o termediate level was cut into pillars by drifts and crosscuts, and mined as on up This saved many raises and allowed greater use of cars instead of barrows.

78. Sub-level Caving in Utah and Arizona

Mercur, Utah. OREBODIES are low-grade gold and silver-bearing replacement deposits in tough, hard limestone, underlying sheets of porphyry which follow the limestone bedding planes on both strike and dip. There are several sheets of porphyry, and in places corresponding parallel orebodies overlying each other. Deposits are 4 to 70 ft thick; dip, 0° to 30°. Ore is usually soft, sometimes like clay; drilling is done single-hand or with augers; 30% dynamite is used. The porphyry hanging wall is blocky and generally caves readily. Practice of CONSOL MERCUR GOLD MINES CO is described below; this company suspended operations in 1913. DEVELOPMENT. Entry is by a compound shaft (Art 17), the lower part being vertical; at each level a crosscut is run through the orebodies, with a drift along each body. Inclines are often sunk in ore from main levels and drifts turned off from them alternately to right and left at 50 ft apart, measured on dip.

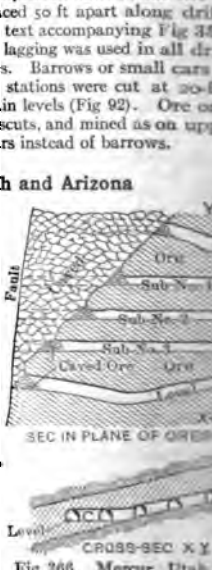

Fig 366. Mercur, Utah. level Caving

Thin beds (less than 20 ft thick; description by G. H. Dern, Bib, 295). Fig 366 shows part of an oreshoot cut off on one side by a fault. g 367. Mercur, Utah. Sub-level Caving

development consists of driving crosscuts *S* from s. Mining begins on the highest sub-level; ends of crosscuts next to hanging wall are widened out until two or more crosscuts are connected, the roof of excavation being temporarily supported by stulls. To start caving, a few holes are drilled in the back next to the hanging wall. Pillars between crosscuts are worked back toward footwall by driving successive slice-drifts, 6 or 7 ft high, across them; slices are timbered with 3-piece sets. Ore is handled to chutes in barrows. Shoveling along face of cave is stopped when much waste appears, and a new section of the back is allowed or forced to cave, a safe working place being kept

ub-level Caving

s all done by hand, no heavy blasts are fired, and light ot started in any area until the sub-level above has ning ore in blocks, caving may be carried on simulta-

neously on several sub-levels at different points along the strike. Thickness of ore on each sub-level is 4 to 7 ft; or from 30 to 50% of the orebody is broken by caving; remainder is obtained in drifts and slices. Results of work indicated that a 12-ft between sub-levels might be better; a 4-ft back could be kept under better control and higher extraction than a 7-ft back. It is difficult to extract all the ore along the especially where the dip is flat. Where this method was used, ore was fairly firm, but ng wall was weak. Timber and powder consumption were low; labor cost, high. tract prices for mining, 60¢ to $1.40 per 1.25-ton main-level car; day's pay miners per 8 hr. Daily output, 700–800 tons; output per man-shift underground, about

Arizona Copper Co, Morenci, Ariz. Fig 368 (P. B. Scotland, 1915) shows a sometimes employed in the upper part of an orebody preparatory to top-slicing. evels are 20 ft apart vertically; intermediate hand-tramming levels, about 75 ft. Interval between raises, 20 ft; ground is mined in blocks 40 ft wide. No mat grade of ore recovered is seriously decreased by mixture with waste (178).

79. Summary, Sub-level Caving

General. Sub-level caving is adapted to large-scale work in large, weak bodies (see Suitable orebodies, Art 76). It is safe, and when properly cond will yield a high extraction and produce clean ore. Disadvantages are in g the same as for top-slicing (Art 75); see comparison below.

Requirements (*a*), (*b*), (*d*) and (*f*) for top-slicing (Art 75) apply direc sub-level caving; other essentials for the successful application of sub caving are: (*a*) Weight of caved ground is necessary on top of working orebody must be wide enough to permit free descent of gob. (*b*) Waste, large amounts, prohibits sub-level caving, as it can not be stowed undergr Waste horses must be broken unless large enough to divide the deposit sections which can be worked independently. Some grading of iron ore is po (Chapin mine, Art 77). (*c*) Boundaries of orebodies should be fairly regul

Sub-level caving *vs* top-slicing (Art 75). Relative ADVANTAGES of sub caving: (*a*) Cost of breaking ground is lower. (*b*) Less timber is required. Larger daily output is possible from a given area. (*d*) Natural ventilati generally better, and there is less timber to be hoisted to working places; conditions and plan of work determine whether sub-level caving has any iority in these respects. Relative DISADVANTAGES of sub-level caving: Percentage extraction is slightly less, and there is always a greater chan losing ore. (*b*) Mining is not so clean; more waste is mixed with ore. Less sorting is possible in slices; grading of ore is more difficult. (*d*) Cavi overlying ground is not under such close control.

Factors of relative cost, percentage extraction, clean mining and co predominate in making a choice. Top-slicing is better in very soft ground is used where its higher extraction produces ore rich enough to offset its hi cost, and where admixture of waste would lower the metal content of ore ciently to impair its market value. Under other conditions, sub-level cavi preferable. Block-caving is a possible alternative for sub-level caving (Art

80. Block-caving

General. The orebody is divided into large blocks, which are then under one at a time, and allowed to fall. They are caved in descending order, from top of the orebody. Under proper conditions, the ore crushes by its own we and that of the overburden into pieces of suitable size for handling. The sett and crushing require time, often several months, during which mining and velopment proceed in some other part of the mine. This method develo from sub-level caving (Art 76) by increasing the height of ore caved in one op tion. Some pillar-caving methods (Art 85–88) are varieties of block-cav Following paragraphs presuppose a knowledge of details obtainable from Art

STANFORD LIBRARIES

Timber mats for separating capping from caved ore are rarely feasible in They may be formed as described in Art 71, but can not be built up nor repa ing begins (Detroit Copper Co, Art 81).

Extraction varies from 70% or less, with careless work under conditions, to 90% with careful work under favorable conditions; data are available. Extraction is affected by: (*a*) size of block; (ore, walls, and capping; (*c*) mode of drawing caved ore; (*d*) spacin

Following experiments at Inspiration mine (Art 81) indicate the relatior these factors (see also Art 82). Tests were made in 1913–14 to determine t extraction to be expected in drawing ore through chutes. A 20 by 30-in bc had glass sides and a wooden bottom in which 0.5-in holes, representing chut on the corners of 1.25-in squares. On a scale of 1 in to 5 ft, this box repres of ore, 150 by 100 ft by 125 ft high; the bottom holes represented chutes 2 6.25 ft apart. By plugging some holes, the interval between chutes cou The box was filled to a given height with crushed ore, upon which was pla crushed capping. The ore was drawn through the chutes, and the percent and dilution with waste were determined by weighing and assaying the ma Dark red, barren rock represented capping, the color of the ore being ligh the definite line between ore and capping could be watched through the drawing proceeded. Experiments were made with the box filled to depths 35 and 70 ft of ore, overlain respectively by 35 and 55 ft of capping. Chut 6.25, 8.87 and 12.5 ft were used and the size of particles of ore and cappin In some tests, drawing was done uniformly and in small quantities at a ti chute; in others, chutes were drawn direct to capping, one at a time.

Conclusions from the above experiments: (*a*) Extraction is increased by i height of ore column and by decreasing distance between chutes. (*b*) Ex clean ore, before capping appears at the chutes, is improved by uniform dra chutes and by decreasing the amount drawn at one time from each chute; not give the highest total extraction for a final product containing 1% Cu. tion increases with coarseness of the particles of ore and capping; fines dec tion, the lowest result being obtained when both ore and capping were fi (*d*) When a uniform limit of grade is allowed at the end of chute drawing, t increases with the % Cu in the ore. (*e*) Assuming that when the ore cav the same volume as in place, the total extraction increases with the amount development and undercutting.

In deciding what extraction could be expected at Inspiration mine in cav average ore 35 to 70 ft high, the results of tests 1 and 2, Table 55, were co servative, provided the chutes were closely watched and no ore below the limit was drawn. Results of tests 3 and 4 were judged obtainable when the the caved ore is strong enough to allow closer spacing of chutes. These result that the capping will break up like ore and not into a fine sand. For details, s

Table 55. Ore-drawing Tests, Inspiration Copper Co, Miami, Ari

scuts, 7 ft wide by 8 ft high. A narrow overhand

STANFORD LIBRARIES

stope is carried to the level above along both foot and hanging walls. Pillars are then removed in slices 8 ft wide, parallel to the strike. This work starts in the pillars along the hanging wall and retreats to footwall; the back of each slice is allowed to cave before starting another. Caved ore is extracted as at the Pewabic mine.

This variation would be used where ore does not separate readily from the walls, or where the walls are irregular; more isolating stopes might be necessary at ends of blocks. Both open and shrinkage stopes have been used for isolating blocks; the former are preferred in the Lake Superior districts (286). This mode of undercutting blocks allows the use of timber for temporary support of ore too soft to stand when undercut, as in Fig 370.

Mowry mine, Ariz. Data from R. B. Brinsmade in 1907 (153). Argentiferous lead carbonate ores occur in irregular steep-dipping pipes or shoots, on a granite-limestone contact. The ore is mostly soft and crumbly, with much clay, Fe_2O_3 and MnO_2. Fig 372 shows method of mining a shoot about 65 by 180 ft in horiz section. A vertical shaft is sunk at each end of the shoot; at vertical intervals of 150 ft, the shafts are connected by drifts *D*, from which crosscuts *C*, 25 ft apart, are driven to the walls. A square-set stope (Art 45), 2 sets high, is then opened over the entire area of the deposit. Tops of 1st-floor sets are lagged, numerous chute-gates are built in the sill-floor sets, and the sides of the 1st-floor sets over the chutes are lagged with 2-in plank. The lagging over the chute-sets is then removed and the overlying ore caves into them. By drawing from all chutes uniformly, t to settle vertically, and distortion of the sets is avoided; some sets always re

Fig 374 its, recently designed e maintenance costs. considerable settlement without destroying the chute-gates and the posts of the upper sets, the latter may settle without affecting the clearance between the chute lip and the top of the car. The very low maintenance cost of this timbering is said to effect a substantial saving, although its first cost is higher than that of ordinary drift-sets.

Weaker ore may be mined by block-caving with this form of timbering than with the Tobin method, but its application is limited to ore which will stand unsupported over areas sufficient to allow erection of the sets. Chutes may be close together over the whole area of the block, to permit uniform drawing of caved ore. Undercutting in soft ore is completed a few feet above the timber by barring through holes made for that purpose. After caving begins, ore must be drawn fast enough to keep excessive weight off the timbers.

Detroit Copper Co, Morenci, Ariz. Data from W. L. Tovote in 1910 (280). For ore occurrence, see Art 74. DEVELOPMENT. Main haulageways and intermediate hand-tramming levels are opened as for top-slicing (Art 74). Two-compartment raises, put up to the capping from the highest intermediate level, are 4 by 6 or 5 by 7 ft in section, and are at the corners of 30-ft squares or 25 by 30-ft rectangles. Commercial mine, Bingham, Utah. Data from R. B. Brins-
made in 1907 (153). Orebodies are large lenses of low-grade
ore, formed by replacement of beds of limestone; they are 200
to 500 ft long and 30 to 70 ft thick. Practice here indicates the
possibilities of block-caving in thick, flat-dipping beds. An
inclined shaft follows the dip of the limestone; level interval,
100 ft. Ore is caved in 50-ft blocks (Fig 377). Inclined raises *R*
driven on the footwall are connected by the sub-level drifts *A*
and *B*; an intermediate sub-drift *D* and raise *S* are then driven.
Three raises *T*, from drift *D* to the hanging wall, are connected
by drift *E*; inclined raises *F* and drift *G* are next driven under
the hanging (see dotted lines in sec *UV*). All ore thus far
broken is handled through chute-gates in sub-level *A*, at the
foot of raises *R* and *S*. The pillars under the hanging wall,
formed by drifts *E* and *G* and raises *F*, are cut away (see sec
UV); footwall pillars between drifts (*B*, *D*) and raises (*R*, *S*)
are reduced to a similar shape. Holes are drilled in all pillars,
also in the backs of *B* and *D*, and in the raises *R* and *T*. The
holes in the hanging-wall pillars are fired first, then all others,
the block of ore breaking off along a vertical plane through raises
T. Caved blocks are allowed to stand and crush, and are then
drawn through gates in sub-level *A*. Successive 50-ft blocks
are similarly caved; work on each sub-level retreats from the
ends to the middle of the orebody. Caving is not begun on
any sub-level until the one above it is worked out.

crosscuts are first driven on the sub under attack (Fig 385), forming pill square, these being small enough to be partially crushed by weight of the o

The mode of caving varies; in places it is quite irregular; usual routine is shown by Fig 386. From a raise nearest the caved ground, a short drift *D* is driven and heavily timbered. A pear-shaped stope *C* (a "chance") is then opened with short holes and light shots; it is enlarged in steps (see numbers 1, 2, and 3), until it becomes unsafe to enter and the adjacent ore caves into it. At first, ore is shoveled to raise *R*; later, caved ore runs to it with little shoveling. When mat appears at its entrance, the "chance" is boarded up or allowed to cave. Usually 3 "chances" are opened around a raise; 2 of them are shown at *C* and *E*. Fig 386; the third is started from angles to *C* and *E*, and, depending on the location, extends to the wall or

olicable, gives a lower mining cost than any other y for large-scale work. In its different forms (Art of various shape and to ores of various strength, but s. In unsuitable deposits, or where carelessly con- at of any other method; systematic work, careful sential to success.

common to all caving methods (Art 83), are: . Vein-like deposits should dip over 65°, and hich, for ideal conditions, the ore should part walls by opening isolating stopes, the cost of e deposit is very wide. Block-caving may be sufficiently thick, preferably at least 70 or 80 ft. ine (Art 81) is applicable to inclined beds 30 ep enough for ore to run on it. The physical break up under block-crushing can not yet be adapted to moderately soft or moderately

STANFORD LIBRARIES

hard, but not to very soft or tough ores. Homogeneous ore of grade is necessary, as no underground sorting can be done. The cave when the underlying ore is dropped; weight of overburden aid in crushing the ore. The most favorable capping breaks int soft, brittle capping decreases extraction. A capping differing from ore is desirable, for ready detection at the chutes at the operations. (See below, Pewabic method *vs* block-caving into ch

Advantages of block-caving: (*a*) Safety. (*b*) Cheap min little drilling, blasting and timbering are done per ton of ore; amo ment is relatively small. (*c*) Production is centralized, allowing vision. After caving begins, a large and easily varied output is one level. (*d*) Natural ventilation is good, compared to that i methods. DISADVANTAGES: (*a*) Preparing the blocks for caving and considerable outlay. (*b*) Extraction is often low, and the danger of losing large amounts of ore. See also below.

Pewabic method *vs* block-caving into chutes. ADVANTAG method (Art 81): simplicity and relatively small amount of de ton of ore caved. DISADVANTAGES: cost and trouble of driving a timbered drifts through caved ground, and necessity for shoveli Block-caving into chutes obviates shoveling, but the developmen plicated, chutes often clog, and maintenance cost of drifts on tra frequently high. For modes of minimizing these difficulties, see of the Tobin method (Art 81). In making a choice between block-caving, the strength and character of ore and capping are fac important than the above. The Pewabic method is limited to fa because, under each block, there must be an open stope, large eno to settle and crush. Block-caving into chutes is adaptable to m Thus, at Inspiration mine, drifts are the largest excavations whic open while a block is being undercut. Broken ore from pillar through the chutes, to provide space for settlement and crushin fications of Pewabic method (Art 81).

Some ore is lost in all block-caving, by mixing with capping when the ca This loss is greatest under a non-coherent or brittle capping, which wh fine and sifts into the ore; it can be minimized by uniform drawing over t block. Use of chutes allows fairly uniform drawing, impossible in the which is therefore applicable only to deposits overlain by strong rock, bre caved. This was the condition at the Pewabic mine, where the cappin zontally-bedded sandstone (208). In general, the Pewabic method ha limited field of use than block-caving into chutes.

Vertical *vs* inclined or branched chute-raises. Relative inclined chute-raises: (*a*) They are easier to construct, and if pro are less apt to clog. (*b*) For a given spacing they require less drif cutting on tramming-levels and subs where ore is undercut (con 375 with Fig 380, 383, Art 81). Conversely, for a given first cos velopment, they may be spaced closer than vertical chutes, wh for uniform drawing over the whole area of a block (see Table are applicable in softer ground, since with vertical chutes the practically unsupported, while the tops of raises are funneled ou sub-level pillars are cut away. (*d*) They collect the ore as draw tively few points on the sub-level below the caved block. Grizz stalled at such points and large lumps spalled before entering the haulageways (Fig 383). With vertical raises, the ore must be trammed from many different points. (*e*) Gates can be operated i

ab where the ore is undercut; hence, when draw-
wn down only a short distance into the chutes.

to stronger ores. A weak, friable capping favors top-slicing; str which breaks large favors block-caving. Sub-level caving alway position intermediate between top-slicing and block-caving. Wh exists, it usually lies either between top-slicing and sub-level caving sub-level and some form of block-caving; for detailed comparisons, s

COMBINED METHODS

84. General

Term "Combined method" designates here a group of mining volving a systematic use or combination of two or more of the meth in Art 29–83. Such methods vary widely and are difficult to classify They are employed chiefly in mining large bodies of soft or hard or they are for large-scale work and aim at a high extraction.

Combinations used generally involve subdivision of the orebody of alternating pillars and stopes; the stopes are usually shrinkage various methods for mining pillars (see Table 57). Combinations

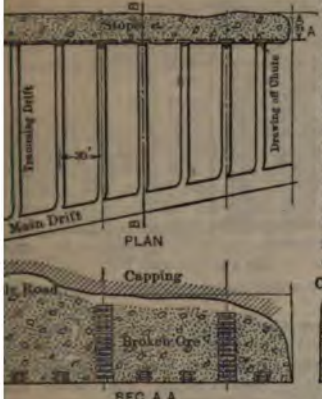
stopes and block-caving are also known as "Shrinkage Stope and I or more simply as "Pillar-caving" systems. The South African d use combined shrinkage stoping and sub-level caving (Art 89), dif in principle from pillar-caving.

85. Practice at Boston Mine, Utah Copper Co

General. SHRINKAGE STOPES AND PILLAR-CAVING were used for by the Boston Consol Co, but were abandoned in 1914 after the been acquired by the Utah Copper Co, which it adjoins. This tended its opencut (Art 97) into the Boston ground and ceased mining there. The present Ray mine method (Art 86) was deve from the Boston method; its evolution illustrates many essential mining of large, low-grade orebodies by shrinkage stopes and pillar-c are two variations, based wholly on differences in mode of handling TRAMMING SYSTEM, in which stopes are opened directly over the d levels and the ore is handled there in small cars to chutes conn haulage level below; (*b*) SUB-LEVEL OR MOTOR-HAULAGE SYSTEM, in begins from a sub-level above a motor-haulage level and the ore i to the latter through chute-raises; the sub-level is a stoping bas BODY is a large, low-grade, disseminated copper deposit, in monzo overlain by a leached capping. It was opened by two adit level vertically, the upper reaching a max depth of 200 ft below the Following data were published by L. A. Bl

ramming system. In the early stages, the plan shown in Fig 388 was tried. the center line of the stope nearest the ore boundary was widened to 20 ft. as carried up a shrinkage stope, access to which was through "pole roads" (Art e ends of alternate tramming drifts. At first, excess ore was shoveled at the ends of the drifts; later, chute-gates were erected in each drift to eliminate shoveling. DISADVANTAGES: (*a*) max output was limited to that which could be produced from one stope; (*b*) the broken ore in the stope drew down on one side, making it difficult for machinemen to work; (*c*) as cars had to be loaded at the end instead of the side, they slopped over, and much shoveling was required to clean the tracks; (*d*) the widening of the stope floor on the level wasted time and money, as the space so formed was filled with unrecoverable ore; (*e*) final extraction was low, as ore in rear of stope could not be recovered.



8. Boston Mine, Hand-tramming System; Chutes at One Side of Stope

Fig 389 shows a later plan. Chute-gates, 30 ft apart on each side of the stope, made it possible to draw the swell of the broken ore more

nd to secure higher final extraction; also several stopes could be worked simul-. But, with the chute-gates so arranged, the miners had to work at times in e of the stope, where the back was continually sloughing off, and in starting a e ore had to be shoveled from the middle to the sides. Ventilation was poor, the gave trouble, and the other disadvan-he plan in Fig 388 persisted. More-large openings caused by placing the from the tramming drifts opposite each kened the bases of the pillars, making to maintain the tramming drifts.) shows the final stage of the hand- system, before underground mining The development work was halved by amming drifts in alternate pillars only; were staggered, reducing the size of their entrance to a minimum. Two were erected in cut at the stope provide gates stope instead of des. The stope e above the level stead of a series apexing at the This important ent did away ensive drifting ing on the stope

Fig 389. Boston Mine, Hand-tramming System; Chutes on Both Sides of Stope

made it possible to recover all the broken ore. *Manway* raises were put up in pillars at 60-ft intervals along *tramming drifts, small crosscuts* from them fur-ccess to stopes. *This mode of entry was later replaced by* manway pillar drifts *because the pillars cracked and the raises became unsafe.* Manway drifts were *d ground, but in presence of seams and faults they caved;* also the drifts

crosscuts on the level require much retimbering. The arrangement of chutes in t required a tram uneconomically long for hand work. The detail of caving pilla drawing ore was not worked out; added drifts have been needed on the levels to extract the pil

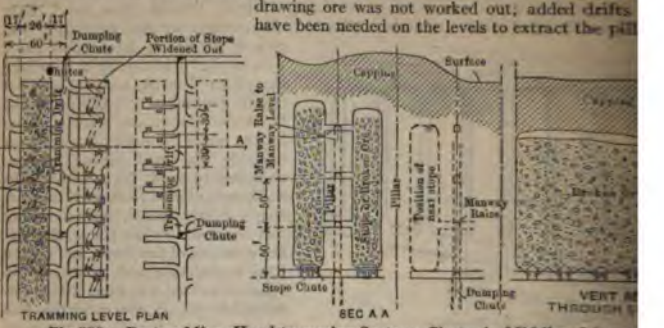


Fig 390. Boston Mine, Hand-tramming System; Chutes in Middle of Stope

Sub-level or motor-haulage system (Fig 391, 392). Stopes are at right angles drifts on the motor level and are opened 30 ft above it by widening the stope d which connect the tops of the chute-raises; the latter are spaced 25 ft apart along lines of stopes. The manway entra stopes gave trouble in this as in the tramming system. At first, raises w up from the motor drifts 100 ft apart center lines of alternate pillars, with throughs at 50-ft vertical intervals pillars usually faulted or sloughed bel

surmounted by pony-sets (Fig 395); angle braces and filler blocks are ground. Chute-gates (Art 91) are built in the pony sets every 12.5 ft a 2 gates being placed opposite each other in each set. Alternate pairs o chutes"). 25 ft apart, serve for drawing ore from stopes; the others ("pillar way between the stope chutes, are for drawing pillar ore. Outside of the orebody, there are no pony sets in drifts *C*; the drift sets have 12 by 14 caps and 10 by 12 collar braces. STAGE 3: Manway drifts, stope drifts and chute-raises. While driving drifts *C*, the 1st sub-level, 30 ft above, is opened. Manway drifts *K*, Fig 393, are 5 by 7 ft and 100 ft apart; they are 12.5 ft to one side of corresponding drifts *C* below, for connecting with raises *L* (Sec *AA*, Fig 393). Stope drifts *S* are driven 25 ft apart over the entire orebody, and are directly over the stope chutes on the motor level. Chute-raises about 6 ft diam are then put up from the stope chutes, on an

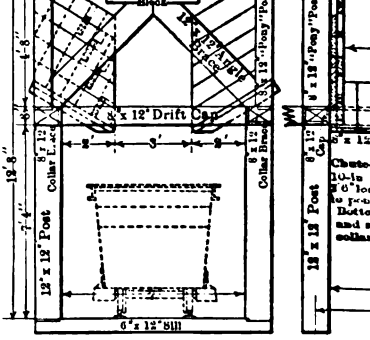

Fig 395. Ray Motor-haulage System, Drift S and Chute-gates

incline for 10 ft and then vertically to the stope drifts. On the 2nd sub drifts *N* are driven directly over drifts *K*. STAGE 4: Manway raises, bel raises, widening stope drifts, building manway sets. Manway raises are *N* at 25-ft intervals along drifts *K*; as their centers are 7.5 ft from centers they are bisected by the stope wall; chain ladders are hung in these raises. chute-raises are funneled while driving manway raises; this is done with sto in uppers. Stopes are started by drilling a line of holes slanting into the s drift; these holes and those drilled in belling the chute-raises widen the

e drifts *K*, directly under the manway raises, as soon y consist of drift-sets, on 8 by 8-in stringers projecting manways are built up from these sets through the STAGE 5: Mining stopes to the capping. For mode lso EX 5, Table 31, Art 28. The broken ore swells s are abandoned when the stope is halfway to the 2nd rough the manway raises. In hard ground, stopes are ore, 10 to 15 ft wide. STAGE 6: Before drawing the y one of the following methods. Method 1 (Fig 396), re 15 to 20 ft wide, leaves narrow pillars easily under- pillar chutes (2nd stage), start in the pillar nearest nnecting the raises along a pillar, they are widened, l. This is repeated in successive pillars, retreating (Fig 396) is used in soft ground, where pillars are wide en along center lines of pillars, 22 ft above the motor

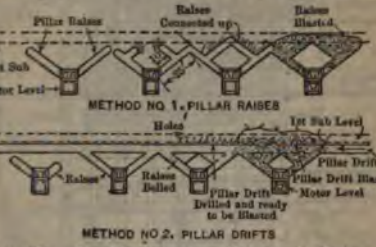

Fig 396. Ray Motor-haulage (6th stage), Undermining Pillars

ing breaks to the surface along a nearly vertical plane where haulage drifts are to be abandoned, the chutes er than the others, so that the capping assumes a slight ne the drifts take weight, all the ore beyond is drawn, ng. Only a few cars of ore are drawn at a time, to ing, with minimum loss and dilution of ore. When empty cars through the fringe drift into the back ends re trammed to the chute. A chute blaster or loader ushes it toward the main drift while another spots an rade in favor of the load. When an 8 or 12-car train the main drift, returning the empties to the back end ficiency results when only 2 trammers and 1 loader are mmers, 3 loaders, 2 machinemen (for blasting boulders nan (for repairing damage to chute-gates by blasting), of 150 tons per 8-hr man-shift. A boss, a timberman hecker are employed in each reserve-drawing section. ther detail.) STAGE 8: Cone-drifting. After all chutes , the ore below the sub-level in the pillars between the mbered "cone-drifts," parallel to drifts *C*, are driven on pillars (Sec *AA*, Fig 393). Chutes are built opposite ifts. A small shrinkage stope directly over the drift is r of the 1st sub-level. Ore is trammed to a winze at otor level. When all the cone-drift chutes are drawn s are mined by slicing. Thus, all ore above the motor- d.

Motor haulage is applicable only in orebodies of large area and of a height exceeding 100 ft; otherwise the cost of driving and timbering the stope laterals and of equipping and maintaining the haulage levels is not justified, and HAND TRAMMING is more economical. ADVANTAGE OF MOTOR HAULAGE: it is suited to large outputs, especially during reserve drawing, when the output is limulage and hoisting plants. ADVANTAGES OF HAND bodies: (*a*) lower initial development cost; (*b*) less , as chutes can be built in every set in both the r haulage, the pillar between the sub and motor

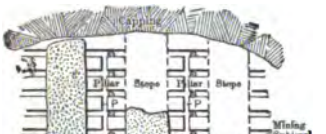
87. Practice at Miami Copper Mine, Ariz

Orebody (see Art 74). The mining system described below was applied relatively hard ground containing 2 300 000 tons.

General plan. Shrinkage stopes and pillar-caving were used; stopes, 5 200 to 500 ft long; pillars, 50 ft wide. Originally the pillars were to be r level stoping (Art 43), leaving broken ore in the stope, but it was difficult to holes, and a shrinkage stoping and sub-level caving method, similar to that (Art 89), was finally adopted. C simultaneously from both shrink stopes, to make the capping This is called locally the WID PILLAR SYSTEM. Following da lished by D. B. Scott in 1916 (



CROSS-SEC THRO STOPES AND PILLARS

Fig 401. Miami Method

Development comprises a ha drawing-off level, the sub-level and raises for handling ore and stopes (Fig 401). Added sub- was necessary to determine the the orebody; its general outline churn drilling (Art 11). HAULA 50 ft below the stopes. By drift long axes of both stopes and pillars (Fig 402), trains of cars could be loa entire stope without uncoupling; this allowed the rapid drawing of excess or during stoping. Also with chutes 25 ft apart, this plan requires a minimu development. 10 by 10-in timber was used in haulage drifts, with 9-ft posts and 8-ft caps; sets, 6.25 ft apart (Fig 445, Art 91). DRAWING-OFF LEVEL, a distinctive feature of this method, was 25 ft above the haulage level; it consisted of drifts parallel to those on the haulage level, with a fringe drift at each end for entry and ventilation (Fig 403). Drifts were on center lines of stopes to secure a symmetrical arrangement of raises for drawing ore (Fig 401). For convenience in putting up vertical development raises in the pillars the pillar drifts were 5 ft off the pillar axes; ment was later modified so that symmetrical drawing raises were possible also The drawing-off level drifts were timbered with 10 by 10-in sets 5 ft apart, usi

In mining pillars, crosscu halfway between the original one-s drilling faces. After crosscuttir vanced on the top sub, the end undercut by uppers drilled outwar of the central drift and the end cro shoveling was done for setting broken ore, and long holes were Usually, no ore was broken on the highest sub nearer than 10 ft to the ca working faces sloping about 45° (Fig 409) were opened successively at the in lower subs. Fig 410 shows routine of drilling in retreating along a sub. The first round from the drift and crosscuts broke to about 12 ft above the sub; the 2nd round, for which long bits could be used, increased this height to 20 ft. Holes were often drilled to the broken ore above, but the remaining 5-ft arch usually caved. Attempts were made to drill 5-ft holes in the floor of the sub, to assist subsequent caving of this arch, but the ground "raveled" so badly that the collars of these holes had to be cased with 3-in pipe to prevent fitchering. These holes broke poorly and were given up. Excess ore was shoveled to raises *P*, Fig 401, and to intermediate raises in the pillars.

Fig 408. Horiz Sc Showing

raise was abandoned and covered by broken ore, lagged stulls were placed

Fig 409. Miami Method, Mining Pillars

below the sub-level. This is imp mining; if raises were not cover would "pipe" down through th proper breaking. As each raise mining on the next lower sub, a s form was built, and the stulls ab out. Mining on the lowest sub the pillars, was subject to modifi by the pony raises, which halv between the regular 25-ft draw raises were funneled in retreatin of the pillar. Funneling was n than 25 ft ahead of pillar breal undercut the entire width of pillar. To protect drillers in case broken ore in the raise, machines for drilling the back were set on 10-in stringers acros

Drawing broken ore systematically began on completion of about 70% of all stope and pillar-mining; no drawing was permitted within 100 ft of any active mining. Drawing of a stope next to a pillar in process of being broken was tried, and caused the pillar to crush and sway. The weight on the drawing-off level during the drawing period varied greatly at different points; at first, some ground was very heavy, with apparently no weight in other places. Probable causes: (*a*) Combined height of capping and ore in northern part of sec 465 ft; in southern part, 350 ft. In the northern section, some drifts re retimbering; in the southern, only 20% needed repair. (*b*) In one small se

Mining other blocks, as prop Mine block No 2 (Fig 415) and then fill with waste to about 20 ft a back over level No 2. Fill the re and 2 by shooting down the cappin drill holes. After filling these bloc 3 by top-slicing. Simultaneously 4 and 5 like 1 and 2. Repeat this successive blocks along the strike.

Advantages of shrinkage stopi caving: (*a*) it is cheap, because o breaking ground and its small sumption. It saves about 20% per t as compared with top-slicing (Art tilation is good; (*c*) it is safe if pro

Requirements for pillar-caving: of large area; (*b*) orebodies with de aries; (*c*) ore that will stand unsupported in the stope backs; (*d*) ore of f grade, little sorting being possible underground; (*e*) ore which will not pack that will stand unsupported while mining the blocks. These requiremen dently rigid, the method in this form has a limited application.

New Jersey Zinc Co's mine, Franklin, N J. Data from H. H. Hodgkinson in 1916 (309). OREBODY is trough-shaped, of franklinite, willemite, zincite and calcite, in crystalline limestone; it has sides of unequal height and pitches at a gentle angle. The ore in the legs of the trough is 12 to over 100 ft thick, compact and tough, but not very hard (307, 98). GENERAL PLAN OF MINING. Entry is by a 965-ft vert shaft and a 1 500-ft incline. Level interval, 50 ft. A combination of shrinkage stoping and top-slicing is employed.

Shrinkage stopes, 17 ft wide, are run from wall to wall (120 ft), leaving 30 to 50-ft pillars. On completing and drawing a 50-ft lift, the stopes are filled with waste from the surface and lift above is started. Of the ore in pillars, 73% is mined by top-slicing and 23% by shrinkage pillar-stopes.

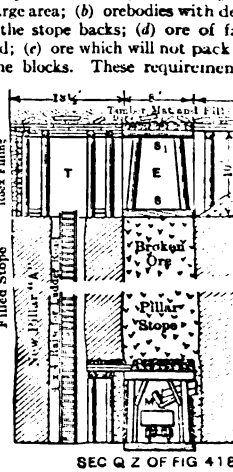

Fig 417. Mining Pillars, N

Mining pillars was started from the top downward, after the stopes at o orebody were completed (Fig 417, 418). A 10 by 8-ft crosscut *M* is driven

1 080-ft level (Fig 421) shows a typical layout for electric haulage. The main crosscut always connects with the prospect shaft and runs to the far wall of the deposit. SUB-LEVELS (Fig 422). Drifts and crosscuts are driven on 22.5-ft centers or multiples of this number. The ground on the sub-level is first cut into pillars 90 to 270 ft sq; all drifts must be exactly over one another on successive subs. Short drifts 22.5 ft apart are driven to rim rock from the nearest drifts and crosscuts, which sufficiently develop the subs to allow stoping to begin. Sub-level drifts are 6 ft wide and 7 ft high, and rarely require timbering. Wider drifts in blue ground usually have 3-piece sets of round timber averaging 10 in diam, and lagged with 2 or 3-in plank. WINZES, 6 to 10 ft diam, connect the subs and haulage level (Fig 420–4 chutes and ladderways, and furnish adde for fast work. Fig 435. Round Timber Cribbed Chute, Section 16 Mine, Ishpeming, Mich

Cylindrical wood-stave chutes (Fig 436) are preferred to cribbed chutes in large filled stopes at Broken Hill South mine, N S W (314). The level interval is 150 ft. In cribbed chutes (Fig 434), the lining cut out rapidly; the spikes holding it also failed and the planks ripped off. Repairs were excessive and even 4-in lining was inadequate. Cylindrical chutes worked better. They are built in 4-ft sections, of beveled staves. Since the grain of the staves is vertical, the cutting action of falling ore is minimized. The staves are bound with wire hoops while filling is being placed around them.

There are 4 types of chute in this mine: (*a*) chute of 4-ft internal diam, with 10-in staves; (*b*) 3-ft chute with 10-in staves; (*c*) 3-ft chute with 6-in staves; (*d*) 3-ft chute with 5-in staves; 5-in thickness is the minimum for sufficient bearing between staves and for resistance to collapse. Type (*a*) is used for the lower 35 ft of both vertical and inclined chutes (its large diam minimizes clogging); type (*b*) is for vertical chutes, for the sections from 35 to 70 ft, when t ft; type (*c*) is used from 70 to 120 lifts, and from 35 to 70 ft on 100-ft (*d*) is for repairing rectangular ch have failed. The upper 30 ft of the mined by underhand square-settin and hence chutes are not required. Staves are of eucalyptus, sawed from roun timbers. At first, dowels, as in Fig 436, were used to hold the staves togethe could be wired, but as this construction was too slow small dogs (cramps), of 0.5-in iron, are now employed. Successive lengths of chute are simply stood one upon another, as they do not tend to move laterally after being enclosed with filling. Fig 437 shows an inclined stave chute. Fig 438 shows a connection between vertical and inclined chutes; the loosely hanging rails yield to every blow and take wear at the turn.

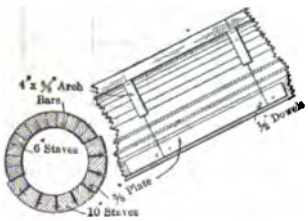

Fig 437. Inclined Cylindrical Chute

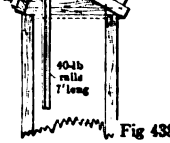

Fig 438

Stave chutes are marked by low first cost and good wearing qualities; they may be withdrawn on finishing a stope. They are serviceable for lining raises and passes for handling filling. E. J. Horwood stated in 1916 that an essential condition for their satisfactory use is that the pressure be approx equal on all sides; hence they are not applicable in stopes having a h ing-wall (242). Table 58 gives the cost of stave chutes, compared with rectangu chutes at Broken Hill South mine. Eucalyptus costs $56.40 per M bd ft; r Oregon pine, $45.60; 2 by 10-in Oregon pine, $48 per M. See Bib (314) for d

tes is prohibited. Clogged chutes are loosened by a le by boring a 2-in hole in a piece of 5-in shafting and r to fire a projectile at the hung-up ore. ADVANTAGES chutes: (*a*) moderate first cost and excellent wearing mall size permissible without undue tendency to clog, he chance that men may fall into them; (*c*) adaptabil- onditions, as no special care is needed when blasting them; (*d*) their impervious structure, which prevents and keeps out sand filling (a difficult matter in wet e and cheapness of erection, each section fitting the one mine the steel chute worked as well as any timber otion in any case depends largely on the relative cost ber.

steel chutes (14 by 14.5 in) are used in filled square-set ennial Eureka mine, Utah, for handling high-grade ore fines. They are of $\frac{3}{16}$-in plate, bolted to 1.5 by 1.5 es at the corners and on the outside.

tes may be started: (*a*) by climbing up the chute and hot which will unkey the clog (dangerous work, which ibited); (*b*) if there is a manway compartment, by he chute; (*c*) by using a "cannon" (see Steel chutes); ays effective and causes delay; (*d*) by a 1 by 1.25-in ron hoops on one end. Extra lengths of rod are lashed nt the rod from catching. The hanging ore is poked

STANFORD LIBRARIES

until it falls, or a stick of dynamite is fastened to the rod and exploded at point. This device can be used up to a height of 100 ft (316).

Fig 441. Chute-gate, Homestake Mine

Chute-gates, at bottoms of chutes, control the flow of ore in loading into ca design and details vary widely. Followi points are important: (*a*) The cheapest that will do the work without undue m cost and delays due to clogging is the b cost should be considered in connection wi tonnage passed; elaborate designs are warranted only by large tonnages. (*b*) Gates must be suited to the size of the ore. Simple board gates serve for fine ore; other forms are necessary for handling large lumps. (*c*) For rapid loading, mechanically operated gates are sometimes required. (*d*) Strength is essential, as wear is heavy and gates must often withstand blasting of boulders in or above them. (*e*) Clearances must be ample, to provide room for barring, to allow for settlement of supporting timbe prevent men from being injured by getting pinched between chutes

2" pieces spiked on

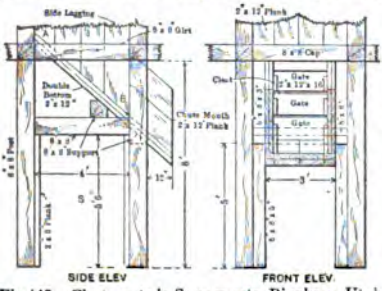

Fig 443. Chute-gate in Square-sets, Bingham, Utah

Following examples are found good under differ tions; see also Bib (31

Simple chute-gates The gate-boards are he cleats; small chutes may board, but 2 give better co flow of ore and facilitate large lumps (Fig 399, Art a larger chute with 3 bo small size material the l *B*, Fig 441, is pried up wi bar; notch *A* is a conven place for board *B* when is running freely. Fig 4 simple chute supported o

der a narrow shrinkage stope; chutes for mill holes in filled stopes are similarly Fig 443 is a chute for square-set stopes (66). The bottom of such chutes is c idly, especially by hard siliceous ore, when the chute is not kept full. Linings of plank, old rails or steel plate, are useful. Wear is reduced by offsetting chute (Fig 445), so that solid rock forms chute bottom. In square-sets, same result is obtainable by lagging chute sets on level and omitting bottom boards *AB*, Fig 443; space *S* then fills with broken ore, which stands at its angle of repose above chute lip and takes the wear. Fig 444 shows a gate and manway in a shrinkage stope (Utah Copper Co), where stope floor is opened at the cap of sets on level (122). See also Fig 404, 406, Art 87.

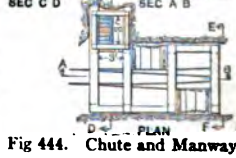

Fig 444. Chute and Manway, Utah C

All the above chutes are designed for loading fine ore into small cars, as in h ming. Board gates for large cars on motor-haulage levels may be similarly s

equired for headroom and for clearance between the conditions practice favors pony-sets for supporting 87, and Fig 395, Art 86).

ed in the Miami mine on motor-haulage levels for he gate ("guillotine" type) is a steel plate, sliding the pony-set posts, and e is rarely as large as (154).

hout damaging timbers; (*c*) the ore settles evenly, the stope instead of from one side; (*d*) rapid drawing is possible, as several cars may be filled simultaneously. DISADVANTAGES: (*a*) higher cost; (*b*) the platform is only 5 ft above the rails, thus reducing headroom for trammers; (*c*) boards *A* are not easily moved when covered with ore; (*d*) the level timbering must be higher above the track, which involves more shoveling in opening a stope.

A modification of the Chinaman chute (see dotted lines in Fig 446) is used at the Copper King mine, Ariz. A 2-in cleat *D* is spiked to the inside of each platform stull; on *D* 2 by 6-in stringers *E* are fitted between the stulls; on *E* loose crossboards *B* are laid. Two of the boards *A* are permanently removed, and the drawing is regulated by boards *B*, which are easily removed and replaced. At this mine, the platform was raised to give headroom in the drift (83, 317).

"Bulldozing chutes" (Fig 447) are used in the Alaska-Gastineau mine, under shrinkage stopes where the ore contains many large apart; pieces passing the grizzly readily go through in the bulldozing chamber. The 2 pockets together balanced it is easily operated by 1 man standing on

mill holes, by the Copper Range Consol Co, Mich. the edge of the car when loading. It is inexpensive and well adapted to the Baltic method (Art 64), because, as the mill holes are used alternately as chutes and ladderways, the gates must be dismantled or installed when the change is made.

fesabi

Hanging chutes (Fig 451) are used on Mesabi Range while mining the lowest sub-level in top-slicing (Art 71, 72). They have the advantage of holding several cars of ore in a short vertical distance, and so avoid interference between miners on the sub and trammers on the main level. The sub-level track is carried on short drift-sets, which also support the rds, rests on 30-lb rails, which run lengthwise of the the rails hang from the caps of small sets just high evel. The chutes are sometimes 20 ft or more long, by removing some of the bottom boards (35).

ng Ore in Flat Stopes

as the breast stopes of S E Missouri (Art 30), apen LOADING costs by employing mechanical . Various devices are also used to cheapen he levels. This problem is especially serious ncrease operating costs and often add to the he level interval (Art 20). Minimum dip on 33° to 45°, depending on character of ore and o° cars may be run directly to the stope faces; ort is difficult.

laid on the stope floor. Table 59 gives a cost record; 2 men ran the shovel and Feb loaded buckets were trammed by hand 400 ft to a shaft; mule used in Mar. As the ore-body was only 12 to 15 ft thick, the shovel had to move frequently to get its ore. (See Art 30 for contract prices for loading buckets by hand in this district.) The shovel was installed not so much to reduce costs as to overcome difficulties caused by an insufficient and irregular labor supply. The MYERS-WHALEY machine, made at Knoxville, Tenn, for shoveling and loading, is oper pressed air or electricity. It runs on the mine tracks and is self-propelling. end is a toothed shovel or scoop, which is thrust into the ore pile, lifted and d ward onto a conveyer, which delivers to an inclined conveyer loading into rear. The shovel is supported on a jib, which swings sidewise so as to cle ore within a 10-ft radius on each side; the conveyer is carried on a sim allowing the use of a double loading track behind the machine. E. H. Lesli the data in Table 60 on work in breast stopes at Flat River, Mo (Art 30). was driven by a 22-h p motor, 1 man controlling all its movements. Th

to 34°, are used at Golden Cross mine, Cal, for dips of about 30°, as d
raising at this mine in Art 22 (116). Similar chutes are used for cleanin
Mohawk copper mine, Mich (Art 40). Stationary chutes are cheapest
and simplest. During blasting they may be protected by piling ore on
each side. In a few cases on the Rand, a small stream of
water has been used to assist movement of ore, when chutes
are nearly at the critical angle.

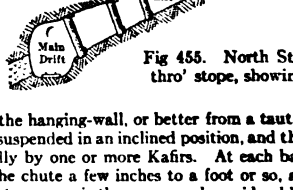

Fig 455. North St
thro' stope, showin

Shaking chutes, widely used in flat stopes on the Rand, are best liked of the stope conveyers, and are especially suited to the local conditions.

They are shallow, sheet-iron troughs, of curved cross-sec, hung by chains from eye-bolts in holes in the hanging-wall, or better from a taut turnbuckle (Fig 457). The chute is suspended in an inclined position, and th into it while it is swung longitudinally by one or more Kafirs. At each ba the ore moves by its inertia down the chute a few inches to a foot or so, a almost continuously. In large, flat stopes, ore is thus conveyed considerabl two or more chutes in series; also, the successive lengths may be placed at

and, chute lengths are 8 ft long by 18 in wide, of
slips into upper end of the next one, and is fastened by 2 bolts fitting loosely in slots, to allow flexibility. As the stope face advances, the chute is lengthened, to keep within shoveling distance (325). Fig 458 shows a chute of ¼-in plate, reinforced by straps (324). On slopes less than 8° or, 10°, ore will not move forward efficiently. See *Jour* Chem, Met & Min Soc of So Af, Oct, 1916, for note of a crank device giving quick forward acceleration and slow return, for chutes on very flat dips; it is operated by a small electric or compressed-air motor. See Combined stopes (Art 41) as to having stope faces parallel to the dip, so that chutes may be set at the max possible slope. Long chutes may be swung by an air cylinder mounted on a

94. Choice of Underground Metal-mining Metho

General. The selection of a method of mining for a given orel by making an inverted statement of the limitations and applica methods already described, but no concise statement can be frame the variations that occur in nature. Usually several methods are adapted to the size, shape, and attitude of the orebody, and th its ore and wall rocks; from these a choice may be made or a me which will best suit the geological, economic, and local conditio Table 62 groups the mining methods for this purpose; it sugg available under ordinary conditions, each of which may be studied with peculiarities of the orebody in question. A mining method i from all viewpoints; it is generally a compromise between confli

Cost and extraction. A low-cost method yielding a low ex give greater total profit than a more perfect method which reco proportion of the orebody.

The following equations (H. L. Smyth) show relations between the fa

$$\frac{p}{p'} = \frac{Q - X}{Q} \quad \text{or} \quad \frac{X}{Q} = \frac{p' - p}{p'}$$

, where Q = total tons of ore in a deposit the most perfect method; X = number of tons abandoned by any other profit per ton by method Q; p' = profit per ton by the other method; p per ton effected by the other method. When $p'(Q - X) = Qp$, the tw equally desirable. The proportion of the deposit which may properly be s

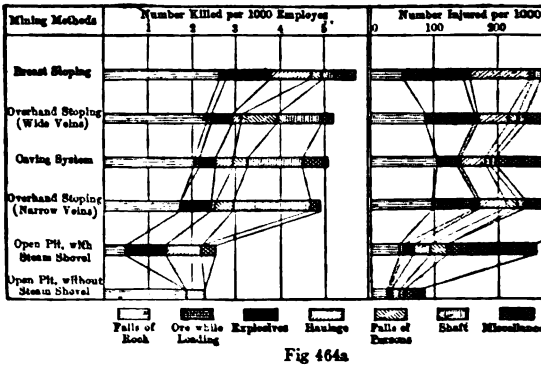

Fig 464a

fore depends on the ratio of the saving to the profit per ton. This rat the profit diminishes, hence for a given saving a larger proportion of ore high value may be sacrificed (172).

Calculations like the above may be elaborated by varying the millin smelter charges on ores of different values; in such cases, the effect of the the point of max profit may often be determined graphically (Fig 86 and

Safety. Few data are available as to the comparative safet mining methods.

Fig 464a shows statistics collected by U S Bureau of Mines for the ye based on returns from 258 mining companies, open-cut mines (Art 95)

OPEN-CUT MINING

95. General

Open cuts ("Open workings," "Open pits," "Open casts") are surface
in connection with coal mining they are called STRIPPINGS. (For quarries, s

Field of use is in mining orebodies that outcrop or lie under sha
The upper parts of narrow, rich veins may be thus mined, with small
and no expense for development; this is a favorite "poor man's
obtaining capital for subsequent work, regardless of ultimate econon
open cuts, involving extensive development and equipment, are o
on the outcrops of wide, veinlike orebodies, because they produce o
than is possible with underground methods. Veins can be worked by
only to a limited depth, largely on account of danger of falls of wall r
walls and flat dips decrease the possible working depth. Open cut
only profitable method of mining thin, flat beds, with shallow cove
99). Large bed-like masses, covered by rock or alluvium, may often
cheaper by open cuts than by underground methods (see Mesab
Consol, etc, Art 97). Large orebodies that can be excavated in
hillside benches are well adapted to open cutting (Art 96). An or
seldom be entirely mined by open cut; underground work is usuall
in depth, and in some cases to mine the ore around the edges of the c

General plan. Open-cut methods are combinations of loosenin
and transporting earth and rock in surface excavations (Sec 3, 5).

The combination selected depends on the shape, size, and depth of pit,
raphy, and output required. Output and method should be adjusted to the
body, to secure minimum cost of production, including interest and amortiza
capital for equipment and stripping. STRIPPING may be completed before
mining, or mining and stripping may proceed simultaneously, when a sur
has been uncovered to avoid interference between the two operations; the
is best, as it reduces the initial investment required before production begins.
may be done in one or more slices, depending on the depth; stripped materi
disposable within a reasonable distance, and at points where dumps will not
subsequent mining. BREAKING GROUND. Open-cut faces are usually worked
(for details, see Art 96-101). Hydraulicking (Art 99, and Sec 3, Art 10) m
for breaking down unconsolidated material. In general, ground is broken
open cuts than in stopes, because of the large faces and use of heavy blasts.
is by hand or mechanical excavators, depending on the scale of operations;
holes (Art 100) are feasible, chute-gates are used. TRANSPORT (see Sec 3, 5)

Classification. An arbitrary grouping of open-cut methods, based on
loading ore is used in Art 96-100 for presenting details. For small-scale work
and shovel or plow and scraper, see Sec 3. See also under placers, Art 120.

96. Open-cut Work with Hand Loading of Ore

Field of use: (a) in small pits, where total tonnage does not wa
first cost of mechanical excavators (Art 97, 98); (b) in large pits,
location or other features of which make mechanical loading or
methods (Art 100) undesirable, or (c) large-scale work, where labor is

98. Open-cut Mining with Drag-line Excavators

General. Drag-line excavators (Sec 3, Fig 4) for stripping
have booms 40 to 110 ft long, with 1 to 4-cu yd buckets. In soft
the excavator should retreat as the cut advances. Cars are lo
or from a hopper; with small cars, the hopper reduces delays and
large area reached from one position of the machine adapts it to st
shallow for steam-shovel work, especially on irregular bedrock.

Mayarí iron mines, Cuba (54). See Art 11 for ore occurrence. T
of orebodies, their softness, and freedom from overburden, favor use o
excavators. Drag-lines are used for ore 20 ft thick or less, when both sur
rock are irregular; steam shovels, tried first, could not clean bedrock wi
it up, and their small radius of action necessitated frequent moves. In
lines, with 2-cu yd Page buckets (Sec 3, Fig 3), handled 1 000 tons per
(346). The excavator works from the original surface, the bucket swing
of 60 ft and readily removes all ore to bedrock for a width of about 100
hummocks of bedrock, stumps, etc, are discarded. Ore is loaded into
dump, steel cars, on tracks on surface. Crew: 1 operator, 1 fireman and 3

20 ft apart along the face. The bank is then blasted down, the grizzlies be with 3 by 12-in plank and a 2 or 3-ft layer of shale; from 2 000 to 3 co down in 1 blast on a group of 3 tunnels. The planks are then removed fr 1 or 2 at a time, starting at the outermost set; the broken shale is bull-do and worked through into cars below. The ridges of shale between the tu by hand. A 3-man crew loaded 2.3-ton cars and trammed them 200 ft an 1.9 cars per man per hr in summer and 1.7 per hr in winter, or 4.37 tons p fore using tunnels, the duty of labor, in loading 2-ton cars by hand from on a 100-ft tram, was 2 tons per man-hr.

101. Miscellaneous Data, Open-cut Mining

Economic limit of depth. Open cutting loses its advantag where the stripping cost per ton of ore exposed exceeds the diff between open-cut and underground mining. For large, flat fairly uniform cover of moderate depth, the problem is simp per ton of ore for excess stripping to provide safe slopes aroun small that errors in its estimation are unimportant. But, on sm for deep overburden, the cost of stripping slopes is important deposits, where one or both walls must often be cut back to s amount of stripping is not a simple function of the depth, an cates calculations of the economic limit of open cutting. In c enough underground and surface mining have been done to e accurate unit costs, close estimates can be made from borings to determine the feasibility or limits of open cuts. The max de able stripping is often expressed in terms of a ratio of cu yd of ton of ore (or ft of overburden per ft of ore).

At Metcalf, Ariz, glory-hole work is profitable when the stripping ra ceed 4 tons of overburden per ton of ore exposed (152). In the anthra stripping ratios are from 2 cu yds of overburden per ton of coal to 4 : 1 Mesabi Range, in 1912, the economic limit was put as follows: (*a*) 1 cu y per ton of ore; (*b*) less than 2 ft of glacial drift to a 1-ft depth of ore (1 or taconite is put equal to 3 ft of drift); (*c*) a max depth of stripping any conditions (35). These ratios are useful if applied intelligently; are many chances for error; ratios applicable in a well-known district m in a new region.

Mesabi estimates (35). Unit prices in 1912 for comparing under and open-pit (Art 97) mining costs were: Stripping glacial drift and per cu yd; stripping broken taconite, 75¢; stripping solid taconite, $1 pe shovel mining, ordinary conditions, 15¢ per ton; underground mining ditions, 75¢ per ton. Sometimes a choice of method can be made by ins estimate (Art 12). Usually the relative cost of underground and open-p be calculated by applying the above unit costs to a column 1 yd sq. drill hole shows 50 ft of drift and paint rock, 15 ft hard taconite, and 36 ore; general conditions allow use of either method. Comparison of costs

Underground mining. Cost of mining a volume of ore 1 yd sq by 36 @ 75¢ per ton (1 cu yd = 2 tons)	
Open-pit mining. Stripping a column of overburden 1 yd sq by 50 ft deep @ 30¢ per cu yd	
Stripping 15 ft of taconite = 5 cu yd @ $1 per yd	
Steam-shovel mining of 36 ft of ore = 24 tons @ 15¢ per ton	
Saving by open-pit work per sq yd of area	

Similar calculations are made for other drill holes, and all are combine to the tonnage represented by each. This preliminary estimate is supplem exact figures when necessary. Questions of adverse topography, dun presence of swamps, quicksand, etc, are local factors which do not permit

Pennsylvania anthracite stripping (145) **(see also Art 97) is gener** when it is cheaper than underground mining. But strippings yield hi

loss, even though a considerable profit comes from
operation, marked advantages must be gained by
g *B* and *C*. Fig 481 shows a crop stripping common
uthern anthracite fields; either the cover must be
, or a thick chain pillar of coal left, as shown. The
w the pillar is minable at as low a UNIT COST for cut-
loading as could be realized by mining the entire
o ft of vein from gangway *W*, after stripping the
len. By the latter method, DEVELOPMENT COSTS
e less by a few cents per ton. But, comparing the
ith the case in Fig 480, the ratio here is 4 cu yd
per ton of coal in the chain pillar, or a ratio of 1 : 1
the total coal above gangway *W*. Hence, the coal
lassed as stripping coal is mined at a loss (345).

Copper Co, N M. Estimates of economic strip-
ts in porphyry copper ores sometimes involve other
, due to fluctuating prices of copper and because
opper may be carried by part of the overburden,
nce it must be excavated, may sometimes be milled
fit. Following formula, used at the Chino mine,
s the mode of determining the lowest grade of rock
y be classified as ore (340).

STANFORD LIBRARIES

102. Choice of Method

The best method in any case is that which will yield a maximum r minimum cost per ton, in the best marketable condition, and with to the miner.

General factors influencing choice and details of method are as

Roof pressure is an indeterminate quantity depending on the depth of longwall mining, heavy roof pressure is advantageous, as it tends to break after it has been undercut, thus facilitating mining at the face. In pillar-min an increase in roof pressure requires larger pillars and smaller openings; thi true in thick seams, or in soft, friable coal. When robbing, the removal of may so shift the roof weight that the adjacent pillars will crush, causing a ger with loss of coal. Foreign practice favors longwall methods for all deep, mo seams, where other factors are at all favorable. American practice employs under all conditions of roof pressure, in both flat and pitching seams; the pil times relieved by artificial supports (Art 110).

Strength and character of roof and floor. The strength of a roof is support itself over mined-out areas. A strong roof allows large opening timbering requirements. A very strong roof transmits the weight to t advantage disappears when, with increasing area of workings, the pressur pillars and causes a squeeze. A roof that will break down and "choke" room is desirable, as it eases the weight on adjacent pillars. In pillar metho facilitated by a roof that is self-supporting over moderate areas, but whi "square" near the working face; this eases the pressure on remaining parts lessens the chance of a squeeze. A hard, brittle roof, that tends to flake of and difficult to manage, requiring narrow openings and much timber. "hangs" over moderate areas and settles gradually is advantageous for lon

The character of the floor also influences the size of openings. A soft bo requires narrow openings and large pillars, especially where firm coal is n strong roof. The pressure on the pillars tends to force them into the floor, a floor to bulge; this is known as a "heave" or "heaving bottom." A firm sirable for all methods of mining.

Character of coal. Strong coal may be mined by either pillar or long The mining of soft, friable coal is always difficult, and in pillar methods pillars. Flat seams of friable coal under heavy cover are best mined by lo character of roof permits.

Inclination and thickness of seam. In general, the maximum allo opening decreases with increasing inclination ("pitch") and thickness Friable coal in a pitching seam sometimes tends to run; this emphasizes the of large pillars and small openings. Practice abroad favors longwall for pi of moderate thickness; in the U S, practically all pitch-mining is done by pi

Presence of explosive gas and dust indirectly influences choice of me a direct effect on the details of all methods. Advancing longwall in a gassy s constant danger of gob fires; hence, where conditions permit, retreating long able. In pitching seams containing occluded gas, the coal often tends to bre the face and pillars (called "bumpy" coal), and requires narrow openings and Where there is danger from explosions of gas or more especially of dust, it is b a divisional or panel system (Fig 505), to confine explosions to small areas. also makes low-velocity air currents desirable and influences the cross-sectio

Product desired. In most cases, the best method of mining is that which the largest amount of lump coal; coal for coking (Sec 35) is an exception. produce the most lump coal; from this point of view under favorable condit methods are best. Excessive use of explosives should be avoided, and syste and haulage carefully designed to avoid breakage.

Character of labor and market. In longwall mining, there must be a s for the product and a steady class of labor; even a short stoppage may re damage to the working face. In pillar methods, this is less important.

194. Room-and-pillar Methods

al. Because of the frequent presence of explosive dust and gas (Sec 14), ventilation is more important for coal than for metal mines. This driving DEVELOPMENT OPENINGS IN SETS. Fresh air enters by one or ings, the INTAKE, and after passing through the workings the foul air mine by other openings, the RETURN.

pment in flat or slightly pitching seams. SINGLE-ENTRY (rarely Sec 14, Art 4). A single opening is driven, from which rooms are turned oe both directions (Fig 484). acts both as a main haulage- an intake airway. The venti- rent circulates as shown. A f may cut off the flow of air. hows a typical DOUBLE-ENTRY Main entries are driven from or from the surface; from these, itt entries are opened. Rooms d off the cross entries. The the split system of exhaust n (Sec 14), the main haulageways being intakes. Advantages: (*a*) in cident in one entry, the other affords an escape; (*b*) the mine is divided ately ventilated sections, so that a fall of roof or complete closure of f butt entries will not affect ventilation in other parts of the mine; (*c*)

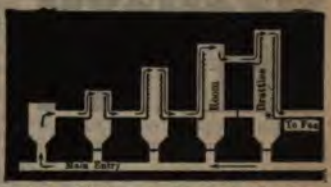

Fig 484. Single-entry System in Flat Seam

Double-entry System in Flat Seam (U S)

main or cross entries may be driven ahead as far as desired and ventilation maintained without turning off rooms. Fig 486 shows TRIPLE-ENTRY applied to main entries, with double-entry in cross entries. The middle entry is the main intake and haulageway; the outer ones form the return. While involving more narrow work than double-entry, this system is well adapted to gassy mines of large working area. It is also used where local conditions (bad roof, etc) prohibit driving a single entry of sufficient width for double-track haulage; the middle entry is then used as the return and the outer entries as intakes and haulageways. In QUADRUPLE-ENTRY, 4 main entries are driven in parallel (Fig 487), of the mine being served by a separate intake and return. One intake y be used as a traveling way, and the other as a haulageway, or both ways. This system facilitates *circulation of large volumes* of air and pted to high-*speed endless-rope haulage (Sec 11)*. By leaving the center *ct. i e, eliminating the* BREAK-THROUGHS *B*, the two sides of the mine

become wholly independent of each other, and may be considered mines, each opened by double-entry. QUINTUPLE-ENTRY is the s preceding, with addition of one more entry, used as a traveling wa

Fig 486. Triple-entry System (Coal Miners Pocket-book)

Entries in flat or slight seams. SIZE of entry depe factors: (*a*) Entries must be l to insure adequate ventilation. prescribe a minimum quantity per man or animal, and a max current (Sec 14). Airways sho minimum perimeter for a giv square entry is preferable to a one. In haulageways, both width are influenced by size method of haulage. (*b*) Cost ing wide openings may be prohi is bad, or the floor has a tender or the coal is friable or easily crushed; in such cases, narrow entries, to drive, are in the end an economy. In seams containing more o or in thin seams, where floor or roof must be blasted to secure headr are usually driven 16 to 20 ft wide and then narrowed to 6 to 10 ft the waste into a packwall along one of the RIBS (Fig 488). (The rib is the face of solid coal along the side of a working.) The extra cost of driving is partly or wholly paid for by the coal taken out and transportation of waste is eliminated. DISTANCE BETWEEN ENTRIES. Main entries in flat seams are commonly driven on 30 to 60-ft centers, leaving, for a 10-ft entry, a 20 to 50-ft pillar. Large pillars are required to protect the main entries during life of mine. Cross entries need not remain open after the area served is exhausted; they are on about 30-ft centers, leaving a 20-ft pillar for a 10-ft entry.

Fig 487. Quadruple-ent

For economy in driving, entries should be as close together as possil the cost of breakthroughs. Distance between sets of cross entries length of room and method of mining; length of room depends on roof, floor, and coal, system of haulage and ventilation. Where room

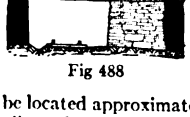

Fig 488

in one direction only, their length is comm 350 ft; where they are turned in both direc length is 600 to 700 ft. DIRECTION AND LOCA largely on the size and shape of the prope conditions, cleavage or CLEAT of the coal (in mines), dip, amount of water, etc. Main en be located approximately to bisect the property. In mines opened b allows development to proceed in 3 directions, reduces the length of and permits final robbing at an earlier date, decreases cost of protrac nance of long haulageways, facilitates haulage, and permits a materia output on relatively short notice. To favor haulage and drainage in sli ing seams, main entries are driven directly on the pitch and cross en parallel to the strike. In bituminous coal, the cleat may alter this plan of driving is often increased if entries are not parallel to one of the cleavage planes. ALINEMENT AND GRADE should be as uniform

e and wear and tear on track and rolling stock, nd hence reduce efficiency of ventilation. Uni- haulage and drainage. Cross-entry haulage- 75 to 1.5%) favoring the load. To obtain this or bottom rock and to fill local depressions, seams may be driven at an angle to the strike following formula (355) is useful: $\sin A = \tan X$ n cross entry and strike of seam, or angle be- room is to be driven on a grade; X = pitch of of seam in degrees (see Table 70). In turning curves should be avoided. This is sometimes CUT-OFFS.

slightly pitching seams. Rooms are usually entry in one or both directions, depending on

Room Centers
24-ft Rooms

Bunting states that, in the application of any formula to the calculation of the size of pillars necessary to resist the pressure of the overlying strata, consideration must be given to the nature of the seam and its contiguous strata, and to the dip. Moreover, the proper factor of safety varies with local conditions, such as the relative location and extent of workings, and the seriousness of possible disturbance to the overlying strata and surface.

nings, DOUBLE ROOMS may be used; they have k on each rib, gob being stored in the middle. Fig rooms. Haulage in rooms, unless mechanical, ha-

comes difficult on pitches of 6° to 8°; rooms may then be turned off obliquel this means of reducing haulage grades in rooms is feasible in seams pitching culations for grade are made as for oblique entries This practice increases the difficulty of robbing pill

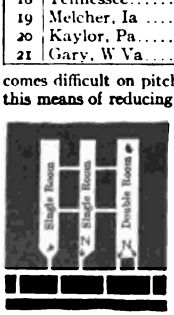

Fig 491

Influence of cleat. Bituminous coals usu two cleavage planes or cleats, running approx at to each other and to the dip. Advantage is taken of them to facilitate breaking down the coal and to release occluded gas by driving the rooms at different angles to the more pronounced cleat. FACE CLEATS are longer and more regular than END CLEATS. Fig 493 shows methods of driving, with their names. In driving FACE-ON, the face of the room is parallel to the face cleats. This is the gene where conditions permit; it requires less powder and undercutting

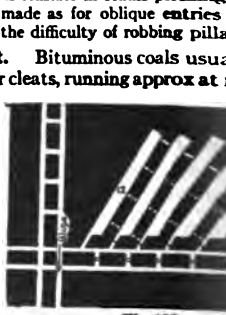

Fig 492

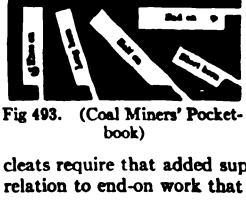

Fig 493. (Coal Miners' Pocketbook)

others, and yields more lump coal. In L work, the room face makes an angle le with the face cleats. Coal breaks in and with well-placed shots there is a fa lump coal. In HALF-ON work, the roor 45° to the cleats; adapted to coals break well on face and end cleats. In SHORT-E the room face is between 45° and 90° cleats; adapted to cases where prono cleats require that added support be given to the coal face and bear relation to end-on work that longhorn does to face-on. In END-ON

room face is parallel to the end cleats; this, with short-horn, is adap stand strong roof pressures, but yields less lump coal than other method containing occluded gas at high pressure, face-on methods may cause bursts of gas, whereas end-on rooms cut the face cleats and allow g gradually. Under these conditions, by using long-horn or short-horn r pressure of gas may be controlled and utilized to assist in breaking dc

Development in pitching seams. The following notes desc anthracite practice, which may be considered standard for the U S. mining, development openings are driven in pairs, consisting of a hau GANGWAY, and an airway or MONKEY. These openings are connected corresponding to the breakthroughs of flat mining. In thick, gassy extra monkey may be added, to provide a separate split of air in ea place. Fig 494 shows typical development for moderately thick variations, see Art 106. SIZE OF GANGWAYS depends more on size method of haulage than on character of coal, roof, and floor, and t seam. Gangways for mule haulage are commonly 7 ft high by 10 tc in the clear. For mechanical haulage the height may be less, th practice leaves at least 2 ft clearance above top of car. DIMENSIO KEYS depend primarily on air requirements (Sec 14); thus, if an area is required to pass the air needed in a split without undue friction, a n 6-ft seam would be 6 ft high. DISTANCE BETWEEN DEVELOPMENT In Penna, the distance between gangway and monkey in moderately t is commonly 30 ft. In thick seams, this distance depends largely c the monkey and gangway are on the same or opposite walls of the is customary to space gangways 300 ft apart along the pitch, leavir PILLAR 20 to 50 ft wide (along the pitch) underneath each gangway This allows a breast length, including the chute, of 250 to 280 ft. Fig 506. Block Room-and-pillar System, Ill

Illinois. Seams are flat; aver depth, 200 ft. is firm, with partings widths; seams, 2.5 to Roof characteristics va generally fire clay, likel when wet. Straight room-and-pillar, panel systems, and a modified panel syst as the "block room-and-pillar" or "semi-panel" (Fig 506), are all in use. For of openings see Table 71 (361). Some long-wall mining is also done (Art 108).

Indiana. Panel systems of room-and-pillar work with double-entry development are in universal use. The following figures of practice of the Brazil Block Coal Co are fairly representative; seams are from 4.7 to 10 ft thick; depths, 80 to 600 ft. Roof is sandstone or shale; floor, fire clay. Rooms, 18 to 30 ft wide, usually 21 ft; necks, commonly 9 ft wide and 12 to 20 ft long. Width of main-entry pillars, 18 to 40 ft; cross-entry pillars, 15 to 30 ft; room pillars, usually 9 or 10 ft wide, occasionally, 20 ft (362).

British practice. Room-and-pillar methods in England (bord-and-pillar, post-and-stall, pillar-and-stall), and in Scotland (stoop-and-room), resemble those in the U S, except in dimensions of openings and percentage of recovery on first mining. Common dimensions (363): entries (walls), 6 ft wide; rooms (stalls), 12 to 15 ft wide; room pillars, as large as 132 to 198 ft square. Recoveries are about 30% to 35% in first mining; first-mining recoveries of 40% to 50% are considered dangerous. Most of the coal is won during robbing (Art 107).

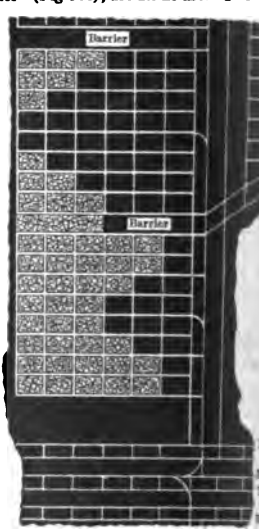

Fig 507. British Practice, Bord-a on Panel System (Hughes)

raises similar to chute-raises, Art 68) are driven to the overlying seam gangways or breasts, or both. Breasts may be opened in the overl directly from the rock-holes, or from small gangways driven to connec of the rock-holes. This practice often effects large economies in dev

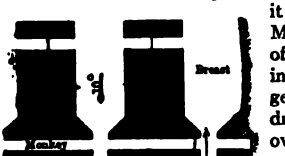

Fig 510. Driving a Gangway Through a Pinch (Natalie Colliery)

it is especially useful in reworking Mammoth seam, which contains large of coal left by the crude early methods. ing old gangways in the Mammoth sea gerous and costly; it is often impossibl drive new gangways in the vicinity of over areas.

One or more contigu may be opened by t across the strata from a ageway in one seam. T poses the possibility of maintaining gangways i seams. Where a series tunnels is driven to reach an adjacent seam they are known as SECTIONAL TU are spaced at intervals depending on their length, speed of development desire condition of the seam to be opened. These tunnels avoid the breakage of co holes, provide numerous working faces and therefore allow rapid devel- opment. Examples of rock-hole practice follow.

Lawrence Colliery, Schuylkill region, Penna. H. H. Morris, Supt, contributes the following. The Holmes seam, averaging 8 to 10 ft of firm coal, is mined by rock-holes from development openings and breasts driven in the Four-Foot seam, which is 5 to 8 ft thick; the seams are separated by about 10 ft of rock; pitch, about 60°. Gangways and monkeys are driven on 30-ft centers in the Four-Foot seam, with chutes turned on 50-ft centers. A few feet above the high side of the monkey a battery is built, and enough coal blasted to allow a 6 by 8-ft rock-hole to be driven on a pitch of about 40° through the top-rock to the Holmes seam. The rock-hole is partitioned off to make a manway and coal chute. On entering the Holmes seam, a battery breast is driven 24 ft wide up the pitch to the desired length. To secure ventilation, 2 or more rock-holes, breasts and headings must be opened in the Holmes; a split of air from the Four-Foot monkey is carried up the manway of one rock-hole, through the workings in the Holmes and down another rock-hole manway into the Four-Foot monkey. After the Holmes breasts have been driven and drawn, breasts of the same width are driven in the Four-Foot seam directly under those in the Holmes. Pillars must all be of the same size. Sometimes the mined coal in the Holmes breasts is held in reserve and not drawn when a breast is finished, in which case an extra battery is built in the rock-hole, for opening the breast in the Four-Foot. In this part of the mine, surface conditions prohibit robbing; it would be feasible, however, to rob the pillars in the Holmes seam before driving the breasts in the Four-Foot. In another part of this mine, several seams, pitching about 65° and 1.5 to 30 ft thick, are mined by counter-gangways, counter-chutes and rock-holes (Fig 512). The colliery is opened by a "gun-boat" slope in the Seven-Foot seam. The main level is at 634 ft elev; counter-levels at 820 and 1 000 ft elev; surface at outcrop is approx at 1 200 ft elev. (In Penna a mines, the elev of gangways is given in ft above sea level.) The method of m thinner seams is about the same as that at the Natalie Colliery (above), excep breasts are of the battery type and worked full. It was found impossible to dr ways in the Mammoth seam, due to the condition of its old workings; hence, r (6 by 6 ft) are driven from the Skidmore or Leader seam at 60-ft centers on the and at 60 ft centers on the pitch from the Skidmore breasts. Interval between and Mammoth seams, 20 to 60 ft. All coal mined on the counter-levels is tra to a counter-chute in the Leader seam (a 12 to 18-in split of the Mammoth app

Robbing Pillars

illars consists in removing the coal left for roof support d. The character of roof and floor, texture of coal, e of gas and other local conditions, all influence the ch it should be done.

re are 2 general systems: robbing during the RETREAT. A further distinction may be made LETE OR FINAL robbing.

shows its application in a flat seam with rooms First-mining is followed closely by preliminary pillars; the stump pillars are left to support the pillars are removed on the retreat system after bbing have been completed to the limit of the d. It is always important to draw the pillars faces in a straight line (Fig 485); this avoids ny one pillar and secures a uniform line of break e line of retreat depends chiefly on the character as robbing proceeds; otherwise the pressure on room pillars may be sufficient to crush them or NTAGES: (*a*) max production per unit area of ss caused by deterioration of pillar coal on long eld of lump coal in soft or friable seams, because pressure can cause extensive crushing; (*d*) im- us mines; (*e*) smaller room pillars may be used,

STANFORD LIBRARIES

due to short life and limited area of support. DISADVANTAGES: (*a*) accumulate in caved areas, which can not be ventilated, and there is alw from fire in such areas; (*b*) where roof strata are water-bearing, the brea roof increases amount of inflow; (*c*) comparatively large stump and entr necessary to prevent squeezes and avoid excessive cost of maintenance

Retreat system is the reverse of the advance. Development driven to their limit, rooms turned, and first-mining is completed thro entire area before robbing begins. Robbing is begun at the inside l area and retreats toward the main or sectional entries; the robbing is *i e*, the room, stump, and entry pillars are extracted in one operation. nation system known as the ADVANCE AND RETREAT SYSTEM is sometimes used where rooms are turned in both directions (Fig 503). Rooms are turned in one direction only as the development entries advance,

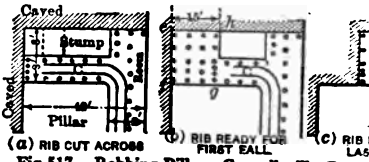

Fig 517. Robbing Pillars, Connellsville Regio

and room-pillar robbing is carried on during the advance. When th the entry is reached, rooms are turned in the opposite direction and retreats toward the main entries, final robb carried on during the retreat.

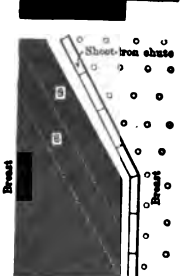

Fig 518. Robbing Pillars, Inclined Seam

Examples of American practice. Details vary underground and surface conditions and the quality of labor available; many cases require special methods. CONNELLSVILLE REGION, Penna. Fig 517 shows pillar-drawing in flat seams. Robbing in any pillar begins at the face of the room and retreats toward the entry. A cut *C*, 8 ft wide, is driven through the pillar, leaving an 8-ft stump next to the caved area. Cut *C* is timbered with props. Cuts are then made across the stump, as indicated by dotted lines in (*a*), and the roof is picked up by props until the work reaches stage (*b*). The props in area *efgh* are next drawn or shot out, forcing the roof to fall. The rest of the stump is then mined and caved, and the process repeated until the whole pillar is drawn back to the entry pillars. The latter are removed by similar methods (358). This general plan, with modifications of detail, is in universal use in the U S for drawing pillars in flat seams. ANTHRACITE MINES, Penna. Methods are unsystematic and often left to the miners. Pillars are usually robbed by taking slices ("skips") off the ribs, the roof being temporarily supported by props. Robbing begins at the upper end of breasts. Fig 518 shows work in chute breasts. Skips *S* are driven at an angle across the pillar, so that the chute may be kept close to the face and loading cheapened. Fig 519 shows a method of robbing on steeper pitches in thin seams. The skips are 5 to 6 ft wide; the direction of work is indicated by arrows. This method is feasible only where a passageway for men and coal can be kept open along the pillar rib. pitches (over 60°) in thicker seams, and where the roof caves close to the pillar ri

Fig 528. Blocking Out Shaft Pillar, Ill

Fig 529

All of the mines are worked by longwall advancing and with one exceptio shafts. The greatest difficulty in starting operations is to form the shaft tablish the working face. Usually in this district, after the hoisting shaf have reached coal, a main entry is driven about 225 ft from each side shaft. From the air shaft 2 entries are driven in opposite directions at the main entry, to the edges of the proposed shaft pillar. The latter is out by driving around it a 9-ft entry *E* (Fig 528), called the "entry-around-pi Large pillars are desirable, to protect the shaft and provide a long working 9-ft entry is then driven around the shaft pillar, parallel to *E*, leaving a 15-ft the two; breakthroughs between the entries are about 42 ft apart. . The "places" are 42 ft long; their limits are marked e to scarcity of labor, about 50% of the "places" are

STANFORD LIBRARIES

worked by 1 miner; the rest by 2 miners. The crew on a "place" is responsible ing packwalls and for gobbing as well as for mining. Where possible an undercu in high and 2 to 2.5 deep is made by picking in the fireclay floor. Sprags are apart; props are set 2 to 5 ft from the face and 6 to 8 ft apart. With an aver undermining, a good miner can undercut about 20 ft of face a day when work clay 8 to 12 in thick. For loading a car, that portion of the coal is taken which standing longest on sprags. These are knocked out, and if the gob has been filled, so that the roof weight rides on the face, the coal breaks from the roof and for loading; otherwise, the coal is wedged down. Under fairly good conditions a of the coal exceeds 1.25-in size.

If the floor is sandstone, or if the fireclay is much over 18 in thick, undercutti in the coal itself; this produces much slack and increases the number of gob fire more fine coal goes into the gob with the waste. To save time and labor the m neglects to support the coal on sprags until the usual 2 ft of undermining is c instead he makes a cut 4 to 8 in deep and pries down the coal. This does not slow breaking power of the roof; dents occur, and more slack and sm result than when full undermining upon. For blasting black powde where necessary. No undercutting are used in the district.

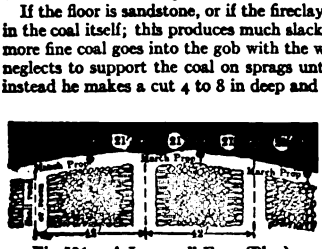

Fig 531. A Longwall Face (Plan)

The rock obtained from brushing that remaining after building the and the clay obtained from underm coal, are piled in the gob area be packwalls lining the roads, to help support the roof and control its pressure on After the first break at the shaft pillar and face, if the gob area has been prop so that the roof weight "rides" on the coal, subsequent roof breaks occur every 2 they parallel the face and extend upward and backward from it at angles of 50 cracks are more nearly vertical on faces which are worked slowly. The distanc breaks depends principally upon the character of roof and the packing of the proper packing it should correspond to the width of coal brought down. The c which breaks extend into the roof depends upon the kind of rock; it rarely exc Squeezes which fill a working place with roof material occur when a room is dri of adjacent rooms, or more commonly when the packwalls are defective and th is not sufficiently filled. There should be enough filling for the roof to co gradually without breaking off short at the face of the packwalls, but not so insufficient weight is thrown on the face of the coal. The better the gob is pa better the coal "works." When part of the working face squeezes, the face is verted to pass around the squeezed area, sometimes leaving a small block of coal

The necessity for artificial humidification to prevent coal-dust explosions ha apparent in these mines. Since all the coal is removed from the seam as the face and the excavation is filled with waste rock, the only sources of dust are the wo and the spillings from mine cars. Dust from the face is covered with shale and in a few days after it is made and does not accumulate. As the aver temperat air in these mines is higher than in room-and-pillar mines, the relative humidity is and considerable moisture is absorbed from the dust of ribs and roads. In a the haulage ways are sprinkled at intervals of 1 week to 3 months (Sec 23, Art 1

109. Breaking Ground in Coal Mines

General. Breaking ground (Art 26) is, in coal mines, sometimes ca TING COAL. The principles are the same as those of breaking ore or roc that coal is relatively soft and brittle, and as a lump product is generally the explosives used are of low power and the number of holes in a giv minimum. No definite rules can be laid down with respect to locatio holes and charge of explosive required, for the following reasons: WIDE ING LOCAL CONDITIONS are encountered in different seams, or in succes in the same seam. Slate partings, "blowing benches," pinches or fau slips, cleat, and the character of the coal itself, whether firm or shelly, experience for properly locating and charging holes. CONTRACT WORK

ork to suit the conditions and keep his laborers busy. power augers, mounted on bars or posts. Recently, small hammer drills, like the Jackhamer (Sec 15), have been successful in driving gangways, especially in the Southern Anthracite Field, where work in thin seams requires the breaking of considerable top or bottom rock. To facilitate blasting and obtain a maximum lump product, coal cutters (Sec 16) are widely used in bituminous mining and to some extent in the Northern Anthracite Field. The chain machines are limited to pitches of less than 20° to 25°; those of the "post-puncher" type are successful in the semi-bituminous coals of Washington on pitches as great as 38° (371).

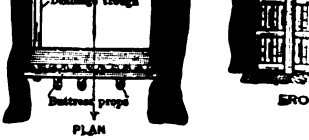
GRAVEL, etc, are efficient, but very abrasive. Though widely used in S
have thus far proved too costly in the U S. GRANULATED SLAG is used abroad in mines near blast furnaces. It is an ideal filling material, having natural cementing qualities and being strongly resistant to pressure.



Modes of handling filling material on the surface, between the surface and the mine, and underground, resemble those described in Art 93.

Few data are available on the lateral distance to which filling may be transported in pipes under a given head. Silesian practice allows 300 ft horizontally for each 100 ft of available head; the distance is obviously affected by size of pipe and thickness of pulp. Water in pulps varies from 40% to 90% of the total volume, depending on grade and size of pipe (or launder), effective head and character of filling material. TROUGHS (launders) (Fig 463) are used where possible

111. Timbering. Use of Steel Supports

Timbering in coal mines is similar to that in metal mines (Art 1 differences in detail and terminology. Props, and 3-piece sets (Art 2 ways, airways, etc, are of round timber.

Common sizes of legs (posts) are 10 to 14-in diam, of collars (caps) 8 to 1 Penna, legs have a batter of 2.5 to 3 in per ft; in bituminous mines they are o Lagging is 3-in round or 6-in split, in 6-ft lengths. Sets are usually 5 ft apa ground they are doubled, at 2.5-ft centers. In moderately thick pitching ways may be timbered with a single row of lagged props along the high side, c to stull timbering in metal mines (Art 36, see also Fig 172). When the le props exceeds about 12 ft, they are replaced by 3-piece sets on flatter dips, or bar" (half or 2-piece sets, Art 21) on steep pitches. Rooms and breasts are ti props set with a slight underlie (Art 36); their spacing depends on the char Headboards are sometimes used; generally props are wedged against the r rooms or moderately pitching breasts, where the roof tends to flake off, c placed between props, at least over the track or chute. For further detail, s

Steel supports are increasingly used in both coal and metal mines for wide openings and those of semi-permanent character, as main ha pumprooms and shaft stations. STEEL *vs* TIMBER. Steel lasts much l cially in moist, foul air. It is fireproof and procurable in sizes tha heavier loads than any available timbers. Less excavation is required erection is usually less than for timber of equivalent strength. Disad steel are its relatively high first cost and the fact that it cannot be reac fitted underground. It may be required by heavy pressures regardl factors; its installation is often justified by saving in maintenance.

Proper size of steel for given service cannot be definitely computed, impossible to measure the weight to be supported. Steel members for repl

continue to the surface. FAULTS AND FRACTURES, if numerous, break t mosaic of blocks, without cohesion; it is as though a girder in a buildi into pieces. Presence of gouge in the faults accelerates subsidence, for it cant; this effect is increased by tures are parallel in dip and stri subsidence will be elongated in t the breaks and its width deter width of the fractured zone. toward the excavation restrict their vicinity, but deflect it so t effects will not be vertically ab The caving along a single faul great, but parallel faults may a between them to move and affec as has occurred in the May Cons Rand. If adjacent faults dip so over the excavation, their effect if they form an inverted V, they

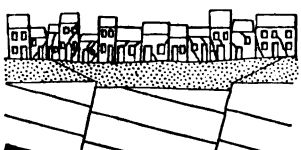

Fig 549. Influence of Faults and Alluvium on Subsidence

supported wedge, ready to drop. This is one of the most dangerous condit ence. In general, faults tend to produce sudden caves. CLEAVAGE (schistosi to occur in the wall rocks of ore deposits than in those of coal seams. If it cohesion is absent in two directions and very small in the third, due to lac of the individual plates. If cleavage is normal to the excavation, the effect on subsidence is much greater than if parallel. FOLDS both aid and hinder subsidence; in case of an anticline above an excavation, the strata, if comprising one or more competent members, may form a supporting arch for the rock above them. If it consist of soft rocks, folding is apt to shear and crush them, which may aid, rather than hinder, subsidence. A syncline over an excavation would aid subsidence, for its nose is apt to be fractured by the bending. BEDDING. Thick, bedded rocks are usually more capable of acting as a unit under stresses, and will support more load than thin beds; their presence would retard or prevent subsidence. Sedimentary rocks overlying ore deposits may be thick or thin bedded; those immediately over coal seams are usually thin be beds, usually thick. DIP OF STRATA overlying coal seams is parallel to th an integral part of the rock series; hence all subsidence breaks across the be discussed in Art 114. In ore deposits, as the bedding may lie at any angle to subsidence is more liable to extend farther vertically when it follows up the d has to break across strata. COMPRESSIVE STRENGTH of the rocks above an ex mines whether subsidence will begin, and if so when. Subsidence may not stone at a given depth beneath the surface, when it would occur in weaker Laboratory tests of rocks can not be safely used to calculate the load they they show the relative strengths. Bunting (468) says tests show that sands manent sets for the smallest loads, while granite and limestone are almost p The average moduli of rupture, in lb per sq in, from a number of tests, are: fi 2 700; slate, 7 736; sandstone, 806; granite, 1 681 (465). For tests on coa

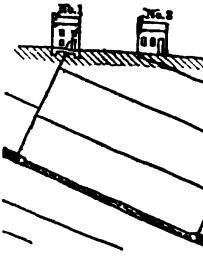

Fig 550. Surface Damag

Underlying rocks sustain the weight transmitted to them through pil excavations. Coal seams are often underlaid by clay which, due to pressu through a pillar, may be forced out into the working and allow the ground side (Table 81, Art 115).

Water-bearing strata above an excavation may be drained, and if shrink, causing surface subsidence. Clays, marls, and clayey sands are produce these results.

Surface alteration may so disintegrate the material overlying an exca that its strength is greatly reduced, and it might allow subsidence to extend

and Principles of Subsidence

are subject to two kinds of distortion due to the with-
oval of mineral: local caving in stopes, and a general
xtension of the local movement may produce general

Empirical formulas are necessary, aided by an approx estimate of strengths of the rocks based on tests. For moduli of rupture, see Art 113. An aver of numerous tests of the Rand quartzite gives a mean ultimate crushing strength of 7 521 lb per sq in (466). Since tested cubes are weaker than the same area in a wide bed, Richardson thinks 10 000 lb is a probable figure; or, at great depths, even 15 000. Taking the sp gr of quartzite as 2.83, the above figures give 8 183 and 12 275 ft, respectively, as the depths at which quartzite will fail under its own weight (Table 78); for inclined strata, multiply the figures in the table by the cosine of the dip. The ultimate strength of trap rock forming pillars in the Lake Superior copper mines is 16 666 lb per sq in (465). Tests of building stone (475) have little value in subsidence; rocks of the coal measures are unsuitable for building. Moisture lowers the crushing strength of sandstone

PLACER MINING METHODS

Introductory. Classification: (*a*) Surface methods which are
of open-cut work (Art 95–101); and of dredging (Art 126). These a
important and varied, since most placers occur at or near the surfac
derground methods for deep or buried placers (Art 116), and kno
Mining or Drifting (Art 127).

Placer mining includes the work of excavating and transporting placer
of recovering their contained gold or other valuable mineral, which is usu
concentrating or "washing" the gravel in running water. All the common
excavating and handling earth and rock (Sec 3, 5) are utilized where suitabl
placer mining, as sometimes used, excludes hydraulicking (Art 122), dredgi
mining; general term "alluvial mining" then includes all methods of mining
Exploration or prospecting of placers, to determine their value and yard
exploitation, is done by drill holes or shafts (Sec 25).

116. Placer Deposits

Definition. Placers are deposits of sand, gravel, or other alluvium, con
ticles of valuable minerals in workable amounts. Native gold is the mos
placer mineral; platinum and cassiterite (stream tin) also occur in gravels
sionally, native Ag, Bi and Cu, amalgam, palladium, cinnabar, monazite, di
other gems; some phosphate deposits (Art 99) may be classed as placers.
"gravel deposit," "gold-bearing gravel," and "alluvial deposit" are used lo
of "placer" or "placer deposit." The following paragraphs deal chiefl
placers; their bearing on other placers is obvious.

Geology. "Three conditions operate to form placers: (*a*) Oc
gold in bedrock to which erosion has had access; (*b*) separation o
bedrock by weathering or abrasion; (*c*) transport, sorting, and de
auriferous material derived from erosion. Erosion, while operati
cases, is not absolutely essential, as residual placers may be form
weathering in place of auriferous bedrock" (377). The primary
PLACER GOLD is almost always in auriferous veins, stringers or othe
These primary deposits were not necessarily rich; they may have be
eroded, or their remnants may not be workable.

Gravel deposits are often concentrations of enormous volumes of rock, in
may have existed in stringers too small to mine. Thus, in the Klondike,
bodies have been found in connection with the placers; the prevailing cou
schist, containing numerous unworkable quartz stringers sometimes showin
produce the present placers, it is estimated that 136 cu miles of rock, averag
2¢ in gold per ton, have been eroded and concentrated. Some gold may
from solution in residual placers; this agency is unimportant in the depositi
formation of nuggets in stream gravels (307, 378).

Weathering and erosion. Deep secular decay of gold-bearing rocks
formation of most important placers; it can occur only in base-leveled regi
graphic maturity. Under such conditions, rocks break down into clay and fi
which are removed by wind and slow-moving water. This effects surface c
of heavy and resistant minerals, and sometimes forms commercially import
deposits, as the aeolian placers of Australia. A subsequent uplift which
the streams will cause rapid removal of the residual mantle and further conc
its heavy minerals along water courses. Placers formed by the concentr
of running water are called SORTED PLACERS. Rapid erosion of fresh ro

placers. A geological history involving several cycles
he formation of rich placers, as deposits of one period

placers are given below and in Art 117; see also Bib (307, 377, 378, 379, ; Geol Surv Bull 328, 337, 410, 498, 533, 534, and 592.

Placers may be classified according to their origin into resi and resorted placers, as above. From the mining standpoint th grouping based largely on form is more useful: (*a*) RESIDUAL PLAC when formed directly over outcrops or on gentle slopes below them times called "eluvial" placers. Residual placers are relatively u their valuable particles are not rounded by abrasion; concentrati is superficial, the richest part being at or close to the surface (379). SIDE PLACERS occur on valley slopes; are not in well defined chann somewhat sorted by water; a transitional type between residual gravels. (*c*) GULCH OR CREEK PLACERS are gravel deposits in, a and at the level of small streams (Fig 568); they are usually shall placer sometimes denotes gravel in gulches which are dry or carry i

streams. (*d*) BEN (terrace gravels) ar of old stream grave moved by subsequ action which has cu to bedrock. They on the flanks of pre (Fig 568), or as rer previous drainage course of which ha relation to existin

The White Channel, in the Klondike, is of the latter type. (*e*) RIVER-B occur in bars and gravel flats adjacent to large streams of gentle grad surface often lies a few ft above normal water level. Fine gold is d existing streams in bars at points where the velocity of the water is chec Art 21). (*f*) GRAVEL-PLAIN PLACERS are formed in flood plains and term is not strictly defined. The wide valley at Oroville, Cal, formed b ing of the Feather river, is a gravel plain; also some of the tundra pla coastal plain at Nome, Alaska (383). (*g*) BEACH PLACERS (marine p formed by the concentrating action of waves on a sloping beach.

Gold in beach placers may come from a sea bluff of auriferous gravel, broke concentrated by the surf; some beaches are probably enriched by gold brough by nearby streams. Nome beach, a famous example, is 50 to 75 yd wide, slopes abuts an escarpment of gravel, muck and tundra 10 to 20 ft high (Fig 569); workable placers occupied 20 miles of beach. Fine gold is concentrated near the bottom of lenticular masses of garnet and magnetite sand, which are 5 to 9 ft thick and normally rest on a clay false bedrock. The lenses are rarely more than 100 ft long, and are not uniformly enriched over the width of the beach. The richest pay was usually in lenses 5 to 6 ft wide by 2 to 6 in thick

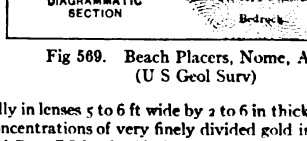

Fig 569. Beach Placers, Nome, A (U S Geol Surv)

Beach placers, consisting of surface concentrations of very finely divided gold i and garnet sands, occur on Kodiak and Popoff Islands, Alaska, on the coast of elsewhere. They are constantly shifting; in places, beaches are reworked annu storms. Beach deposits must usually be mined by simple hand methods (Art 11 disastrous attempts to work them on a larger scale failed to recognise that whil thin layers may be rich, the aver value of any considerable depth of sand i Wave action sorts beach material into equal-falling grains (Sec 28, Art 17); wh

if they strike parallel to a stream course), clay, clayey sandstone gold may work down several feet; it also settles into minute crevi rock; it has been found in solution cavities in limestone to a depth of

In a new locality, the character of bedrock may be inferred from surroun evidence from shafts or boreholes is more reliable than that from exposures in in which decomposed rock would be eroded. Large boulders of adjacent co the gravel usually indicate hard bedrock. Bedrocks of schist, granite, an stone and porphyry, are usually decomposed to a depth sufficient to all In one South American hydraulic mine, a granite bedrock is rotted to a 10 ft; though barren, this material must be washed to recover the gold lyi limestone and slate formations, bedrock is almost always hard and block deep crevices. Creviced bedrock increases costs, as it must be taken up t contained gold. In hydraulic mining, hard bedrock increases cost of bed Bedrock of regular contour is desirable for all placer methods (385).

Character of gold. Placer gold is of all sizes, from large nugget specks called "colors." The size of colors is indicated by the num 1¢ worth of gold; some gold in the Snake River, Idaho, runs 2 000 Gold usually occurs in flattened and rounded grains; angular piec tallized gold, occasionally found, indicate nearness to the primary d

Fine gold is sometimes in thin scales, difficult to save; scaly gold and other forms may be coated with a film of SiO_2, MnO_2 or limonite, which hir mation. Fragments of quartz often adhere to gold, or form part of nugg commonly associated with particles of magnetite and ilmenite ("black sa (ruby sand), zircon and other heavy rock minerals (307). If present in la black sand may pack in riffles of sluices (Art 124) and interfere with gold

Lead in form of shot occurs in placer districts where much hunting has be caught by gold-saving devices and is separated at the time of clean-up; pays to melt such metal and sell it as base bullion.

Placer gold varies in fineness from 500 to 999; it is always alloyed sometimes copper is present; it is usually purer than that in veins district; its purity increases with the distance transported and w creasing size of grains.

Distribution of values may be the determining factor in c mining method. For example, all the gold in a deposit 100 ft d concentrated on bedrock in a 4 or 5-ft paystreak. A high-cost drifting (Art 127) may give more profit than cheaper open-cut wor the handling of 95 ft of barren material.

Frozen gravels of Alaska and Siberia must often be thawed by artificial they can be worked (Art 126, 127).

Buried timber occurs in many placers in the tropics; it is a serious hind may prohibit dredging. It may be piped out of the bank in hydraulic m into pieces for hoisting by derricks. Standing timber increases cost of o by the cost of clearing, which, per cu yd, varies inversely with the depth of

Swell of gravel upon excavation is usually 20 to 30%, up to 50 pact clayey gravel.

Swell may vary in different parts of same deposit; its determination is all sampling work, to avoid errors in estimating values. Several excavatic made and the resulting gravel measured loose in a wooden box holding 1 or percentage of swell is computed from the volume of excavation.

Values in gravel are expressed in cents or dollars per cu yd, or sq yd of bedrock. Drift mines often report values per ton.

Value per sq ft is the most convenient basis in placers where most of t thin paystreaks. If 2 or more paystreaks overlie each other, the total val is obtained by adding the values per sq ft of the separate paystreaks; th than estimates per cu yd. Value per sq ft × depth in ft ÷ 27 = value per

ioveling-in, Horse-scraping into Sluices

shows typical ground-sluicing in shallow creek steep enough to allow it. Sluice *M* is set at the worked and a shallow trench *T* is dug, preferably is deepened to bedrock by turning a stream of picking up the bottom, the material being washed ng bedrock the trench is widened by picking and n. Small plank or earth dams *D*, erected where gainst the bank to aid in undercutting it and so l use forces a stream to do considerable work night shift. Coarse gold remains on bedrock, ce riffles. As the bank recedes, exposed bedrock and scrapers; the concentrates may be cleaned len placed at intervals along the face fork out on cleaned bedrock, as at *B*.

riations. In Alaska, it is often used for cheaply stripuck (Art 117). Tundra and brush are grubbed and be done as in Fig 573, or the water may be led through vening ridges eventually cave; spring floods are thus treams of water may be caused to trickle down the face nels; the ground between caves is blasted or pried off.

STANFORD LIBRARIES

In this way, in 1911, the Granville Mining Co, Dominion Creek, Yukon, muck 18 ft thick, the bank receding 4 to 7 in per day; est'd cost of work, 10¢ per cu yd of muck (393). Such work generally stops on reaching gr sluicing uses water as an excavating agent where pressure water for hydr available. (The term at times der shoveling into ground-sluices.)

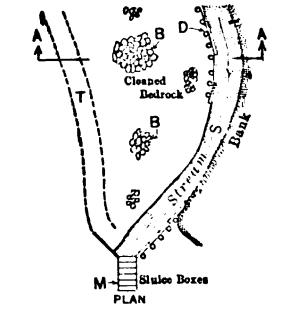

Fig 573. Ground-sluicing (diagrammatic)

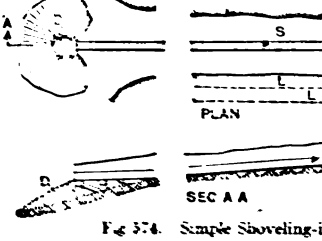
Requirements for ground-sluici gravel, rarely more than 6 to 8 ft d cient grade for the available wat loosened soil. Data covering diffe are lacking. The Granville Co (se muck on grades of 17 to 25 ft per r gravel are much steeper. (*c*) Plentif again data are lacking. Longridge (it takes about 6 times as much wat terial in a ground-sluice as to do the box-sluice. Scanty water supply r be supplemented by pumping bac pools at end of sluice. (*d*) Dumpr at lower end of the sluice may be p natural grade of bedrock or surface are sometimes employed to move ta end of the sluice; worked-out area as dumps.

Duty of water and labor. Mead 2 men can move 20 to 30 cu yd ma day by ground-sluicing (395). A na Swaziland handles up to 10 cu yd of per shift, where a good stream of able (396, 397). In Colombia, in gravel 5 to 15 ft deep, a stream of 135 r 122) moved only 50 cu yd per day (385). Purington gives following data on s (50 to 75% ice) in Alaska. On Anvil Cr, Nome, 400 miner's in of wate high; grade, 4.5 in to 12 ft; duty of water, 10 cu yd per in per 24 hr. Anvil Cr, a 4.5-ft bank of muck was stripped with 100 in of water; grade duty of water, 3 cu yd per in per 24 hr. On Crooked Cr, near Council, 5 bank, 4 ft high; grade, 4.5 in to 12 ft; duty of water, 3.45 cu yd per in p

Booming ("hushing") is applicable where the water supply is inadequ work. Water is impounded above the diggings; and by releasing it at inte gravel through the ground-sluices. Booming is also used for strippin booming usually have gates opening automatically when the reservoir is fu gate is common, controlled by a lever carrying an open box at its outer en voir when full overflows into the box; the added weight lifts the gate, and empties itself. Gates must be so arranged that the dam will not be injured by the rushing water. Booming strips light overburden cheaply. In 1904 on American Cr, Alaska, an area 200 ft long by 20 ft wide was stripped of muck and gravel 5 ft thick in 3 weeks; costs including dam and gate did not exceed 2 cts per cu yd (394). See also (396, 397).



Shoveling-in (*i. e.* into sluices) has its simplest form in shallow creek gravels where bedrock grade is steeper than is required for sluices (Fig 574) or bedrock with the lower end raised and flattened to give headro

Large l are generally usec or wheel scrapers and too difficult loading when dra

In the Klondike, toothed slip-scrapers, holding 0.33 to 0.5 cu yd, ope 30-hp double-drum hoists, handle an aver of 250 cu yd of tailings per fireman, hoistman, and 1 or 2 men to fill, guide, and dump. Scrapers work through horiz distances of 100 to 300 ft and heights of 20 to 50 ft. Aver cost of plant, $3 500 (390).

H. I. Ellis (399) and J. F. Katz (400) give following data on power-scraping in Fairbanks District, Alaska: Bagley scrapers, bottomless or of the wheel type, have replaced other types; in 1914, 15 were in use, most of them operated by 3-drum hoists with cylinders from 7 by 10 in to 10 by 12 in. Creek gradients are flat, requiring elevated sluices to secure dumproom for tailings. Fig 578, 579 show 2 layouts; scrapers may be hauled up an incline, or may dump into cars or skips which are hoisted to the sluice; a large saving in fuel is claimed for the latter method. The 3-drum hoist with 2 tail lines, *T*, Fig 579, allows the scraper to load at any point. In Fig 578, the scraper is hauled by a continuous rope on a single drum; the lead of the pulling rope is changed by shifting sheave *B*. This rig operated a plow and scraper on alternate shifts. At a fairly typical mine (Fig 579), 3 to 4 ft of overlaid by 4 ft of barren gravel and 6 ft of muck. After the muck w
